Chapter 1

Introduction to the Rational Curves

The main results here we follows the famous book [15].

1.1 Hilbert Schemes and Chow Schemes

1.1.1 Hilbert Schemes, a Basic Introduction

Definition 1.1.1. Let X be an S -scheme, we define the Hilbert functor $\mathcal{H}ilb_{X/S}$ sends an S -scheme Z to the set consists of subschemes $V \subset X \times_S Z$ which is proper and flat over Z .

Fix a Polynomial P and a relative ample line bundle $\mathcal{O}(1)$, we can define $\mathcal{H}ilb_{X/S}^P$ sends an S -scheme Z to the set consists of subschemes $V \subset X \times_S Z$ which is proper and flat over Z with Hilbert Polynomial P .

Theorem 1.1.2 (Grothendieck). Let S be a noetherian scheme, let $X \rightarrow S$ be a projective morphism, and \mathcal{L} a relatively very ample line bundle on X . Then for any polynomial P , the Hilbert functor $\mathcal{H}ilb_{X/S}^P$ is representable by a projective S -scheme $\text{Hilb}_{X/S}^P$. We also have $\text{Hilb}_{X/S} = \coprod_P \text{Hilb}_{X/S}^P$.

Proof. Note that this notion of projectivity is much general than [9], but is the same when $S = \text{Spec } k$. The proof is to embed it into Grassmannian. The original proof in [8] and we also refer [20], [15] and [6]. \square

Remark 1.1.3. In [3] we can remove the noetherian hypothesis, by instead assuming strong (quasi-)projectivity of $X \rightarrow S$. So also [1].

Example 1.1.1. Some examples and interesting results:

- (a) We have $\mathrm{Hilb}_{X/S}^1 = X/S$.
 (b) Let C be a curve over a field k , then

$$\mathrm{Hilb}_{C/k}^m \cong S^m C := \underbrace{C \times \cdots \times C}_m / \mathfrak{S}_m.$$

Hence if C smooth, so is $\mathrm{Hilb}_{C/k}^m$. See also [6] Theorem 7.2.3(1) and Proposition 7.3.3.

- (c) Let S be a smooth surface over a field k , then $\mathrm{Hilb}_{S/k}^m$ is also smooth of dimension $2m$ and hence $\mathrm{Hilb}_{S/k}^m \rightarrow S^m X$ (we will see this later for general settings) is a resolution of singularities. Note that $S^m X$ is smooth if and only if X is smooth and $\dim X = 1$ or $m < 2$. See [6] Theorem 7.2.3(2) and Theorem 7.3.4.
 (d) Let X be a nonsingular variety. Then $\mathrm{Hilb}_{X/k}^m$ is nonsingular for $m \leq 3$. Moreover, for any nonsingular 3-fold the scheme $\mathrm{Hilb}_{X/k}^4$ is singular. See [6] Remark 7.2.5 and 7.2.6.
 (e) Let \mathcal{E} be a vector bundle of rank $m+1$ over S and let $P_d(n) = \binom{m+n}{m} - \binom{m+n-d}{m}$, then

$$\mathrm{Hilb}_{\mathbb{P}(\mathcal{E})/S}^{P_d} \cong \mathbb{P}((\mathrm{Sym}^d \mathcal{E})^\vee).$$

- (f) Let $Z \rightarrow S$, we have $\mathrm{Hilb}_{X \times_S Z/Z} \cong \mathrm{Hilb}_{X/S} \times_S Z$.
 (g) **Hartshorne's Connectedness Theorem:** for every connected noetherian scheme S , $\mathrm{Hilb}_{\mathbb{P}_S^n/S}^P$ is connected.
 (h) Let X be a connected variety over k , then $\mathrm{Hilb}_{X/k}^n$ is connected for all $n > 0$.
 (i) **Murphy's Law:** It has many singularities, that is, for every scheme X finite type over \mathbb{Z} and point $x \in X$, there exists a point $q \in \mathrm{Hilb}_{\mathbb{P}^n/k}^P$ of some Hilbert scheme and an isomorphism

$$\widehat{\mathcal{O}}_{X,p}[[x_1, \dots, x_s]] \cong \widehat{\mathcal{O}}_{\mathrm{Hilb}_{\mathbb{P}^n/k,q}^P}[[y_1, \dots, y_t]].$$

See [23]. In fact, it can be arranged that the Hilbert scheme parameterizes smooth curves in \mathbb{P}^n for some n . It turns out that various other moduli spaces also satisfy Murphy's Law: Kontsevich's moduli space of maps, moduli of canonically polarized smooth surfaces, moduli of curves with linear systems, and the moduli space of stable sheaves.

- (j) In [22] they gave a full classification of the situation where $\mathrm{Hilb}_{\mathbb{P}^n/k}^P$ smooth.

Definition 1.1.4. Let $X/S, Y/S$ are S -schemes, then we have a functor $\mathcal{H}om_S(X, Y)$ send S -scheme T into a set of T -morphisms $X \times_S T \rightarrow Y \times_S T$.

For a subscheme $B \subset X$ proper over S and $g : B \rightarrow Y$, we have a functor $\mathcal{H}om_S(X, Y; g)$ send S -scheme T into a set of T -morphisms $X \times_S T \rightarrow Y \times_S T$ such that $f|_{B \times_S T} = g \times_S \mathrm{id}_T$.

Proposition 1.1.5. *If X/S and Y/S are both projective over S and X is flat over S , then $\mathcal{H}om_S(X, Y)$ represented by an open subscheme $\text{Hom}_S(X, Y) \subset \text{Hilb}_{X \times_S Y/S}$.*

Proof. Any $X \times_S T \rightarrow Y \times_S T$ correspond to its graph which is a closed immersion $\Gamma : X \times_S T \rightarrow X \times_S Y \times_S T$. As X is flat over S , then $X \times_S T$ is flat over T . Hence we get a morphism $\text{Hom}_S(X, Y) \rightarrow \text{Hilb}_{X \times_S Y/S}$. We omit the more details and refer Theorem I.1.10 in [15]. \square

Proposition 1.1.6. *If X/S and Y/S are both projective over S and X, B are both flat over S , then $\mathcal{H}om_S(X, Y; g)$ represented by a subscheme $\text{Hom}_S(X, Y; g) \subset \text{Hom}_S(X, Y)$.*

Proof. Consider the restriction map $R : \text{Hom}_S(X, Y) \rightarrow \text{Hom}_S(B, Y)$, then $g : B \rightarrow Y$ gives a section $G : S \rightarrow \text{Hom}_S(B, Y)$. Hence $\text{Hom}_S(X, Y; g) := R^{-1}(G(S)) \subset \text{Hom}_S(X, Y)$ represents $\mathcal{H}om_S(X, Y; g)$. \square

Now we state the deformation theory of Hilbert schemes. We only consider the simpler case that all schemes over a field k . For general case we refer Section 1.2 in [15].

Theorem 1.1.7. *Let Y be a projective scheme over a field k and $Z \subset Y$ is a subscheme. Then*

(a) *We have*

$$T_{[Z]} \text{Hilb}_Y \cong \text{Hom}_Z(\mathcal{I}_Z/\mathcal{I}_Z^2, \mathcal{O}_Z).$$

(b) *The dimension of every irreducible components of Hilb_Y at $[Z]$ is at least*

$$\dim \text{Hom}_Z(\mathcal{I}_Z/\mathcal{I}_Z^2, \mathcal{O}_Z) - \dim \text{Ext}_Z^1(\mathcal{I}_Z/\mathcal{I}_Z^2, \mathcal{O}_Z).$$

Proof. See Theorem I.2.8 in [15]. For family case we refer Theorem I.2.15 in [15]. \square

Corollary 1.1.8. *Let X, Y are projective varieties over a field k with a morphism $f : X \rightarrow Y$. Let Y is smooth over k . Then*

(a) *We have*

$$T_{[f]} \text{Hom}_k(X, Y) \cong \text{Hom}_X(f^* \Omega_Y^1, \mathcal{O}_X).$$

(b) *The dimension of every irreducible components of $\text{Hom}_k(X, Y)$ at $[f]$ is at least*

$$\dim \text{Hom}_X(f^* \Omega_Y^1, \mathcal{O}_X) - \dim \text{Ext}_X^1(f^* \Omega_Y^1, \mathcal{O}_X).$$

Proof. Let $Z \subset X \times_k Y$ be the graph of f , we claim that $\mathcal{I}_Z/\mathcal{I}_Z^2 \cong f^* \Omega_Y^1$. Indeed we have an exact sequence $\mathcal{I}_Z/\mathcal{I}_Z^2 \rightarrow \Omega_{X \times_k Y}^1|_Z \rightarrow \Omega_Z^1 \rightarrow 0$. This is split by $\mathcal{O}_Z \cong \mathcal{O}_X \xrightarrow{(\text{id}_X, 1)} \mathcal{O}_{X \times_k Y}$. Then we can show the claim. Hence the results follows from Theorem 1.1.7. The family version we refer Theorem I.2.17 in [15]. \square

1.1.2 Chow Schemes, a Basic Introduction

Here we only consider the schemes over a field k such that $\text{char}(k) = 0$. The positive characteristic case is very complicated and we refer Section I.4 in [15].

Definition 1.1.9. Let $g_i : U_i \rightarrow W$ be a proper morphism of schemes over W . Assume that W is reduced and U_i is irreducible. By generic flatness there is an open subset $W_i \subset g_i(U_i) \subset W$ such that g_i is flat of relative dimension d over W_i . Let $T = \text{Spec } \Delta$ be the spectrum of a DVR Δ and $h : T \rightarrow W$ a morphism such that $h(T_g) \in W_i$ and $h(T_0) = w \in W$. Let $h^*U_i = U_i \times_h T$ and $\mathcal{J} \subset \mathcal{O}_{h^*U_i}$ the ideal of those sections whose support is contained in the special fiber of $h^*U_i \rightarrow T$. Let $(U_i)'_T := \text{Spec}_T \mathcal{O}_{h^*U_i} / \mathcal{J}$ which is flat over T . Then we let $[Z_0]$ be the fundamental cycle of the central fiber of $(U_i)'_T \rightarrow T$, and define

$$\lim_{h \rightarrow w} (U_i/U) := [Z_0] \in Z_d(g_i^{-1}(w) \times_{\kappa(w)} T_0)$$

which is called the cycle theoretic fiber of g_i at w along h .

Definition 1.1.10. A well defined family of d -dimensional proper algebraic cycles over W is a pair $(g : U \rightarrow W)$ satisfying the following properties:

- (a) There is a reduced scheme $\text{supp } U$ with irreducible components U_i such that $U = \sum_i m_i [U_i]$ is an algebraic cycle.
- (b) W is a reduced scheme and $g : \text{supp } U \rightarrow W$ is a proper morphism.
- (c) Let $g_i := g|_{U_i}$. Then every g_i maps onto an irreducible component of W and every fiber of g_i is either empty or has dimension d . In particular there is a dense open subset $W_0 \subset W$ such that every g_i is flat over W_0 .
- (d) For every $w \in W$ there is a cycle $g^{[-1]}(w) \in Z_d(g^{-1}(w))$ such that for any $h : T \rightarrow W$ of spectrum of DVR such that $h(T_0) = w$ and $h(T_g) \in W_0$ we have

$$g^{[-1]}(w) =_{\text{ess}} \sum_i m_i \lim_{h \rightarrow w} (U_i/W).$$

That is, both two cycles from a single cycle of $Z_d(g^{-1}(w))$.

Remark 1.1.11. If W is normal, then (d) can be implied by (a)-(c). See Theorem I.3.17 in [15].

Definition 1.1.12. Let X be a scheme over S . A well defined family of proper algebraic cycles of X/S over W/S is a pair $(g : U/S \rightarrow W/S)$ satisfying the following properties:

- (a) $\text{supp } U$ is a closed subscheme of $X \times_S W$ and g is the natural projection morphism.

- (b) $(g : U \rightarrow W)$ is a well defined family of d -dimensional proper algebraic cycles over W for some d .

Proposition 1.1.13. *Assume that $g : U \rightarrow W$ is proper and flat of relative dimension d and W is reduced. Let $\sum_i m_i [U_i]$ be the fundamental cycle of U . Then $g : [U] \rightarrow W$ is a well defined family of algebraic cycles over W .*

Proof. See Lemma I.3.14 and Corollary I.3.15 in [15]. \square

Definition 1.1.14 (Chow Schemes of Characteristic Zero). *Let X/S and we define a functor $\mathcal{C}how_{X/S}$ sends Z/S to the set consists of well defined families of nonnegative proper algebraic cycles of $X \times_S Z/Z$.*

Let a relative ample line bundle $\mathcal{O}(1)$, we can define $\mathcal{C}how_{X/S}^{d,d'}$ sends Z/S to the set consists of well defined families of nonnegative proper algebraic cycles of $X \times_S Z/Z$ which is of dimension d and degree d' .

Theorem 1.1.15. *Let X/S be a scheme, projective over S and $\mathcal{O}(1)$ relatively ample. Then the functor $\mathcal{C}how_{X/S}^{d,d'}$ is representable by a semi-normal and projective S -scheme $\text{Chow}_{X/S}^{d,d'}$. We also have $\text{Chow}_{X/S} = \coprod_{d,d'} \text{Chow}_{X/S}^{d,d'}$.*

Proof. Very complicated, we refer Theorem I.3.21 in [15]. \square

Example 1.1.2. *Let X be a semi-normal variety, then $\text{Chow}_{X/k}^{0,m} \cong S^m X$.*

Proposition 1.1.16 (Hilbert-Chow). *Let X, Y be S -schemes.*

- (a) *We have a natural morphism $\text{Hilb}_{X/S}^{\text{sn}} \rightarrow \text{Chow}_{X/S}$. This morphism can be factored by dimensions.*
- (b) *If X, Y be projective S -schemes and X/S flat, then we have*

$$\text{Hom}_S(X, Y)^{\text{sn}} \rightarrow \text{Chow}_{Y/S}.$$

Proof. For (a), consider $[\text{Univ}^{\text{Hilb}} \times_{\text{Hilb}_{X/S}} \text{Hilb}_{X/S}^{\text{sn}}] \rightarrow \text{Hilb}_{X/S}^{\text{sn}}$, then by Proposition 1.1.13 this is a well defined family of algebraic cycles. This gives such morphism $\text{Hilb}_{X/S}^{\text{sn}} \rightarrow \text{Chow}_{X/S}$.

For (b), by (a) we have

$$\text{Hom}_S(X, Y)^{\text{sn}} \rightarrow \text{Hilb}(X \times_S Y/S)^{\text{sn}} \rightarrow \text{Chow}_{X \times_S Y/S} \rightarrow \text{Chow}_{Y/S}$$

and well done. \square

Remark 1.1.17. *Let X be a semi-normal variety, hence we have $(\text{Hilb}_{X/k}^m)^{\text{sn}} \rightarrow \text{Chow}_{X/k}^{0,m} \cong S^m X$.*

1.1.3 Small Applications to Curves

For more applications we refer Section II.1 in [15]. Here we only need some easy case. We assume over a field k .

Theorem 1.1.18. *Let C be a proper curve and $f : C \rightarrow Y$ a morphism to a projective variety Y of dimension n such that Y is smooth along $f(C)$. Then*

$$\dim_{[f]} \operatorname{Hom}(C, Y) \geq -C \cdot K_Y + n\chi(\mathcal{O}_C).$$

*And equality holds if $H^1(C, f^*T_Y) = 0$, in this case it is smooth at $[f]$.*

Proof. By Corollary 1.1.8(b) we have

$$\begin{aligned} \dim_{[f]} \operatorname{Hom}(C, Y) &\geq \dim \operatorname{Hom}_X(f^*\Omega_Y^1, \mathcal{O}_X) - \dim \operatorname{Ext}_X^1(f^*\Omega_Y^1, \mathcal{O}_X) \\ &= h^0(C, f^*T_Y) - h^1(C, f^*T_Y) = \chi(C, f^*T_Y) \\ &= \deg f^*T_Y + n\chi(\mathcal{O}_C) \end{aligned}$$

by Riemann-Roch theorem. The final statement follows from Corollary 1.1.8(a). \square

Proposition 1.1.19. *Assume that X/S is flat, B/S is flat and finite of degree m and Y/S is smooth of relative dimension n . Then $\dim \operatorname{Hom}(X, Y; g) \geq \dim \operatorname{Hom}(X, Y) - kn$.*

Proof. Let $p : B \rightarrow S$ be the projection. By Corollary 1.1.8 we find that $\operatorname{Hom}(B, Y)$ is smooth over S of relative dimension $rank\ kn$. Thus $g(S) \subset \operatorname{Hom}(B, Y)$ is locally defined by kn equations. Pulling back these equations by R we obtain local defining equations. \square

Lemma 1.1.20. *Let $0 \in T$ be the spectrum of a local ring and let U/T be a flat and proper and V/T be a variety. Let $p : U \rightarrow V$ as a T -morphism. If $p_0 : U_0 \rightarrow V_0$ is a closed immersion (resp. an isomorphism), then so is p .*

Proof. See Lemma I.1.10.1 and Proposition I.7.4.1.2 in [15]. We omit this. \square

Theorem 1.1.21. *Let C be a projective curve over k and Y a smooth variety over k . Let $B \subset C$ be a closed subscheme which is finite over k . Assume that C is smooth along B . Let $g : B \rightarrow Y$ be a morphism. Then*

(a) *We have*

$$T_{[f]} \operatorname{Hom}(C, Y; g) \cong H^0(C, f^*T_Y \otimes \mathcal{I}_B).$$

(b) *The dimension of every irreducible component of $\operatorname{Hom}(C, Y; g)$ at $[f]$ is at least*

$$h^0(C, f^*T_Y \otimes \mathcal{I}_B) - h^1(C, f^*T_Y \otimes \mathcal{I}_B).$$

Proof. The original proof we refer [19]. A simple case of family version we refer Theorem II.1.7 in [15]. Here we assume k is algebraically closed. Here $\mathcal{S}_B = \mathcal{O}_C(-s_1 - \dots - s_m)$.

Let $X_0 := C \times_k Y$ and let $\gamma_0 : C \cong \Gamma_0 \subset X_0$ be the graph of f . Let $\pi_1 : X_1 := \text{Bl}_{\{s_1\}} X_0 \rightarrow X_0$ and Γ_1 be the strict transform of Γ_0 . Let $\gamma_1 : C \cong \Gamma_1 \subset X_1$ as C is smooth at s_1 . Repeat the process and finally we get $\pi_m : X_m := \text{Bl}_{\{s_m\}} X_{m-1} \rightarrow X_{m-1}$ and Γ_m be the strict transform of Γ_{m-1} . Let $\gamma_m : C \cong \Gamma_m \subset X_m$. Then we have $\gamma_0^*(\mathcal{S}_{\Gamma_0}/\mathcal{S}_{\Gamma_0}^2) \cong f^*\Omega_Y^1$ and $\gamma_{i+1}^*(\mathcal{S}_{\Gamma_{i+1}}/\mathcal{S}_{\Gamma_{i+1}}^2) \cong \gamma_i^*(\mathcal{S}_{\Gamma_i}/\mathcal{S}_{\Gamma_i}^2) \otimes \mathcal{O}_C(-s_{i+1})$. Hence we get $\gamma_m^*(\mathcal{S}_{\Gamma_m}/\mathcal{S}_{\Gamma_m}^2) \cong f^*\Omega_Y^1 \otimes \mathcal{S}_B$.

Now we claim that there is an open neighborhood $[\Gamma_m] \in U \subset \text{Hilb}_{X_m}$ such that $\text{Hom}(C, Y; g) \cong U$. Indeed, let $U \subset \text{Hilb}_{X_m}$ be the open set parametrizing those 1-cycles D for which the projection $D \rightarrow C$ is an isomorphism. This is open by Lemma 1.1.20.

First, the universal family of U is contained in $\text{Hom}(C, Y; g)(U)$. Conversely consider $[p_0 : C \times R \rightarrow Y \times R] \in \text{Hom}(C, Y; g)(R)$. Let its graph is $G_0 \subset X_0 \times R$. As $\{s_1\} \times R \subset G_0$ and $G_0 \rightarrow R$ smooth along $\{s_1\} \times R$, we let $G_1 \subset X_1 \times R$ be the strict transform of G_0 . Then $G_1 \cong G_0 \cong C \times R$. Repeat the process and finally we get $X_m \times R \supset C \times R \cong G_m \in \text{Hilb}_{X_m}(R)$. Hence this give the isomorphism $\text{Hom}(C, Y; g) \cong U$. Hence by Theorem 1.1.7 and we get the result. \square

1.2 Families of Rational Curves

We may assume all schemes over a field k of characteristic zero locally of finite type. Note that there are also have the same results by some small modification in the case of positive characteristic, see Section II.2 in [15].

Proposition 1.2.1. *Let $f : X \rightarrow Y$ be a proper morphism of relative dimension one. Assume that if T is the spectrum of a DVR and $h : T \rightarrow Y$ a morphism, then every irreducible component of $T \times_Y X$ has dimension two (By Corollary I.3.16 in [15] this is always the case if f is a well defined family of proper algebraic 1-cycles). Then the subset*

$$\{y \in Y : f^{-1}(y) \text{ has geometrically rational components}\} \subset Y$$

is closed in Y .

Proof. See Proposition II.2.2 in [15]. \square

Corollary 1.2.2. *Let $g : U \rightarrow V$ be a family of proper algebraic 1-cycles of X/S . Let $U' \subset U$ be the set of points $u \in U$ which are contained in a geometrically rational component of $g^{-1}(g(u))$. The image of the natural morphism $U' \rightarrow X$ is called the rational locus of g . It is denoted by $\text{RatLocus}(g : U \rightarrow V)$.*

Now let $V \rightarrow S$ is proper, then $\text{RatLocus}(g : U \rightarrow V)$ is proper over S .

Proof. WLOG we let V is irreducible. Let $U = \sum_i a_i U_i$, then we just need to consider every $g_i : U_i \rightarrow V$. Consider the generic fiber D_i of g_i which is a irreducible curve, then if D_i rational, then so is whole g_i by Proposition 1.2.1. Hence $\text{RatLocus}(g_i : U_i \rightarrow V) = \text{Im}(U_i \rightarrow X)$ is proper over S . If D_i is not rational, then there is an open subset $\emptyset \neq W \subset V$ such that the fibers of g_i over W are irreducible and nonrational. Thus

$$\text{RatLocus}(g_i : U_i \rightarrow V) = \text{RatLocus}(g_i : g_i^{-1}(V \setminus W) \rightarrow V \setminus W).$$

Hence we can apply Noetherian induction. \square

Definition 1.2.3. Let $\text{Hom}_{\text{bir}}(\mathbb{P}^1, X) \subset \text{Hom}(\mathbb{P}^1, X)$ be a subscheme correspond to the morphisms $\mathbb{P}^1 \rightarrow X$ birational to its image. By Lemma 1.1.20 since $\mathbb{P}^1 \rightarrow X$ birational to its image if and only if it is a immersion at its generic point, then $\text{Hom}_{\text{bir}}(\mathbb{P}^1, X) \subset \text{Hom}(\mathbb{P}^1, X)$ is an open subscheme.

Definition 1.2.4. Let X/S be a scheme, projective over S .

- (a) Let $\text{Hom}_{\text{bir}}(\mathbb{P}^1, X)^{\text{sn}} = \bigcup_i W_i$ be the decomposition into irreducible subschemes of semi-normalization of $\text{Hom}_{\text{bir}}(\mathbb{P}^1, X)$. By Proposition 1.1.16 we have the Hilbert-Chow morphism $\text{Hom}_{\text{bir}}(\mathbb{P}^1, X)^{\text{sn}} \rightarrow \text{Chow}_{X/S}$. Let $V'_i = \overline{\text{Im}(U_i \rightarrow \text{Chow}_{X/S})}$. By Proposition 1.2.1 V'_i parametrizes 1-cycles with geometrically rational components, and the generic 1-cycle is irreducible. Let $V_i \subset V'_i$ be the open subscheme parametrizing irreducible 1-cycles.

Let $\eta_i \in V_i$ be the generic points correspond to curves C_i . By generic smoothness C_i is a smooth rational curve. Let V_i^{n} be the normalization of V_i . Then we define the family of rational curves on X is

$$\text{RatCurves}^{\text{n}}(X/S) := \coprod_i V_i^{\text{n}}.$$

with a normalization morphism $\text{RatCurves}^{\text{n}}(X/S) \rightarrow \text{Chow}_{X/S}$.

If \mathcal{L} is ample on X/S , then we can define $\text{RatCurves}^{\text{n}}(X/S) = \coprod_d \text{RatCurves}_d^{\text{n}}(X/S)$ where $\text{RatCurves}_d^{\text{n}}(X/S)$ is quasi-projective over S for any d . We define its universal rational curve is

$$\text{Univ}^{\text{rc}}(X/S) := \left(\text{RatCurves}^{\text{n}}(X/S) \times_{\text{Chow}_{X/S}} \text{Univ}_{X/S}^{\text{Chow}} \right)^{\text{n}}$$

be the normalization.

- (b) Fix a section $f : S \rightarrow X$. Similar as (a) we can define $\text{RatCurves}^{\text{n}}(f, X/S) = \coprod_d \text{RatCurves}_d^{\text{n}}(f, X/S)$ and $\text{Univ}^{\text{rc}}(f, X/S)$. This is called family of rational curves passing through $\text{Im}(f)$.

In particular if $S = \text{Spec } k$ where k is a field and $f : (\text{Spec } k) = x \in X$, then we will use the notation $\text{RatCurves}^{\text{n}}(x, X) = \coprod_d \text{RatCurves}_d^{\text{n}}(x, X)$ and $\text{Univ}^{\text{rc}}(x, X)$.

Theorem 1.2.5. (a) *Let $f : X \rightarrow Y$ be a proper and surjective morphism between irreducible and normal schemes. Assume that the dimension of every fiber is one (hence f is a well defined family of proper 1-cycles by Remark 1.1.11). Assume that for every $y \in Y$ the cycle theoretic fiber $f^{[-1]}(y)$ is an irreducible and reduced rational curve, then f is a \mathbb{P}^1 -bundle.*

(b) *In the case of the definition, the universal morphisms*

$$\mathrm{Univ}^{\mathrm{rc}}(X/S) \rightarrow \mathrm{RatCurves}^n(X/S) \text{ and } \mathrm{Univ}^{\mathrm{rc}}(x, X) \rightarrow \mathrm{RatCurves}^n(x, X)$$

are \mathbb{P}^1 -bundles.

Proof. (b) follows directly from (a), so we just need to prove (a).

One can show that f is smooth at the generic point of every fiber (see Theorem I.6.5 in [15]). For $y \in Y$ pick three different points $x_1, x_2, x_3 \in f^{-1}(y)$ such that f is smooth at x_i . Let $S_i \subset X$ be a Cartier divisor which intersects $f^{[-1]}(y)$ transversally at x_i (there may be other intersection points). Hence $S_i \rightarrow Y$ is étale at x_i . Let

$$Z = S_1 \times_Y S_2 \times_Y S_3, \quad z = (x_1, x_2, x_3) \in Z \text{ and } X_Z = X \times_Y Z.$$

So $Z \rightarrow Y$ is étale at z , thus X_Z is normal along $f_Z^{-1}(z)$ and f is smooth above y iff f_Z is smooth above z by some commutative algebra. Furthermore, f_Z has three sections $s_i : Z \rightarrow X_Z$ corresponding to the S_i . By shrinking Z we may assume that these sections are disjoint.

In $\mathbb{P}_Z^1 \rightarrow Z$ we have three disjoint sections $p_i : Z \rightarrow \mathbb{P}_Z^1$ corresponding to $\{0, 1, \infty\}$. Our aim is to construct an isomorphism $q : \mathbb{P}_Z^1 \cong X_Z$ such that $q \circ p_i = s_i$. Let $h : \mathbb{P}_Z^1 \times_Z X_Z \rightarrow Z$ be the projection. In order to construct the graph of q let $\Gamma \subset \mathrm{Chow}_{\mathbb{P}_Z^1 \times_Z X_Z / Z}$ be the closed subvariety parametrizing 1-cycles D with the following properties:

- (1) $\deg \mathcal{O}_{\mathbb{P}^1}(1)|_D = 1$;
- (2) $\deg \mathcal{O}(s_1(Z))|_D = 1$;
- (3) $(p_i(h(D)), s_i(h(D))) \in D$ for $i = 1, 2, 3$.

Let $\mathrm{Univ}^\Gamma \rightarrow \Gamma$ be the universal family. We claim that the natural projections $\pi_1 : \mathrm{Univ}^\Gamma \rightarrow \mathbb{P}_Z^1$ and $\pi_2 : \mathrm{Univ}^\Gamma \rightarrow X_Z$ are isomorphisms.

For any $t \in Z$ consider $h^{-1}(t)$. By construction $(h^{-1}(t))_{\mathrm{red}} \cong \mathbb{P}_{\kappa(t)}^1 \times C_t$ where C_t is an irreducible geometrically rational curve, smooth for general t . As D gives a 1-cycle on $(h^{-1}(t))_{\mathrm{red}}$ which has bidegree $(1, 1)$, thus D is either the graph of a birational morphism $q_t : \mathbb{P}_{\kappa(t)}^1 \rightarrow C_t$ or the union of a vertical and of a horizontal section. In the latter case it can not contain all three points $(p_i(t), s_i(t))$. Hence D is the graph of the unique birational morphism q_t such that $q_t(p_i(t)) = s_i(t)$ for $i = 1, 2, 3$. Thus π_1, π_2 are both one-to-one. If C_t is smooth, then q_t is defined over $\kappa(t)$, thus π_1, π_2 are

isomorphisms over the generic point of Z . Since X_Z and \mathbb{P}_Z^1 are normal, this implies that π_1, π_2 are isomorphisms. Well done. \square

Remark 1.2.6. *In positive characteristic, (a) is right if we assume generic-smoothness.*

Proposition 1.2.7. *Notation as above definitions, then*

- (a) *Let $m = \min\{d : \text{RatCurves}_d^n(X/S) \neq \emptyset\}$. Then $\text{RatCurves}_k^n(X/S)$ is proper over S for $k < 2m$.*
- (b) *Let S be a field and let $m(x) = \min\{d : \text{RatCurves}_d^n(x, X) \neq \emptyset\}$. Then $\text{RatCurves}_k^n(x, X)$ is proper for $k < m + m(x)$.*

Proof. (b) follows from the same proof of (a). For (a), as $\text{Chow}_{X/S}^{1,k}$ is proper over S , we just need to show that $\bigcup_i V_i \subset \text{Chow}_{X/S}^{1,k}$ is closed where $\text{RatCurves}_k^n(X/S) = \bigcup_i V_i \rightarrow \bigcup_i V_i$ is finite. Let $\sum_i a_i D_i \in \overline{\text{RatCurves}_k^n(X/S)}$, then every D_i is rational by Proposition 1.2.1 and $\sum_i a_i \deg D_i = k < 2m$. By assumption $\deg D_i \geq m$, then $\sum_i a_i D_i$ is an irreducible and reduced rational curve. Hence $\text{RatCurves}_k^n(X/S)$ closed. \square

Theorem 1.2.8. *Let $\text{Hom}_{\text{bir}}^n$ be the normalization of Hom_{bir} , then we have the following important results:*

- (a) *Let X/S projective scheme over S , then there is a natural commutative diagram*

$$\begin{array}{ccc} \mathbb{P}^1 \times \text{Hom}_{\text{bir}}^n(\mathbb{P}_S^1, X/S) & \xrightarrow{U} & \text{Univ}^{\text{rc}}(X/S) \\ \downarrow & & \downarrow \\ \text{Hom}_{\text{bir}}^n(\mathbb{P}_S^1, X/S) & \xrightarrow{u} & \text{RatCurves}^n(X/S) \end{array}$$

where U and u are smooth of relative dimension 3 with connected fibers. (In fact both U and u are principal $\text{Aut}(\mathbb{P}^1)$ -bundles)

- (b) *Let X projective scheme over k with a k -point $x \in X(k)$, then there is a natural commutative diagram*

$$\begin{array}{ccc} \mathbb{P}^1 \times \text{Hom}_{\text{bir}}^n(\mathbb{P}^1, X; 0 \mapsto x) & \xrightarrow{U} & \text{Univ}^{\text{rc}}(x, X) \\ \downarrow & & \downarrow \\ \text{Hom}_{\text{bir}}^n(\mathbb{P}^1, X; 0 \mapsto x) & \xrightarrow{u} & \text{RatCurves}^n(x, X) \end{array}$$

where U and u are smooth of relative dimension 2 with connected fibers. (In fact both U and u are principal $\text{Aut}(\mathbb{P}^1; 0)$ -bundles)

Proof. These are easy but boring since we consider the characteristic zero. See [15] Theorem II.2.15 and II.2.16. \square

Corollary 1.2.9. *Let X projective scheme over k with a k -point $x \in X(k)$, then*

$$T_{[C]} \text{RatCurves}^n(X/k) \cong H^0(\mathbb{P}^1, N_C), \quad T_{[C]} \text{RatCurves}^n(x, X) \cong H^0(\mathbb{P}^1, N_C \otimes \mathfrak{m}_x)$$

for general point $[C]$ where $f : \mathbb{P}^1 \rightarrow C \subset X$ is birational and $N_C = f^*T_X/T_{\mathbb{P}^1}$.

Proof. By Theorem 1.2.8, canonical morphism $u : \text{Hom}_{\text{bir}}^n(\mathbb{P}_k^1, X/k) \rightarrow \text{RatCurves}^n(X/k)$ is a principal $\text{Aut}(\mathbb{P}^1)$ -bundle which is smooth. Hence we have

$$0 \rightarrow u^* \Omega_{\text{RatCurves}^n(X/k)}^1 \rightarrow \Omega_{\text{Hom}_{\text{bir}}^n(\mathbb{P}_k^1, X/k)}^1 \rightarrow \Omega_u^1 \rightarrow 0.$$

As $[C]$ general, we have $T_{[f]} \text{Hom}_{\text{bir}}^n(\mathbb{P}_k^1, X/k) = T_{[f]} \text{Hom}_{\text{bir}}(\mathbb{P}_k^1, X/k)$. Hence

$$T_{[C]} \text{RatCurves}^n(X/k) \cong T_{[f]} \text{Hom}_{\text{bir}}(\mathbb{P}_k^1, X/k) / \text{Aut}(\mathbb{P}^1) \cong H^0(\mathbb{P}^1, N_C)$$

by trivial reason. Similar for $\text{RatCurves}^n(x, X)$. \square

1.3 Free and Minimal Rational Curves

We will assume all scheme over a algebraically closed field k of characteristic zero.

1.3.1 Free Rational Curves

Definition 1.3.1. *Let C be a proper curve, X a smooth variety and $f : C \rightarrow X$ a morphism. Let $B \subset C$ be a closed subscheme with ideal sheaf \mathcal{I}_B and $g = f|_B$. We call f is called **free over f** if f is nonconstant and $H^1(C, f^*T_X \otimes \mathcal{I}_B) = 0$ and $f^*T_X \otimes \mathcal{I}_B$ is generated by global sections. Therefore we can define $\text{Hom}^{\text{free}}(\mathbb{P}^1, X) \subset \text{Hom}(\mathbb{P}^1, X)$ parameterizes the free rational curves.*

Proposition 1.3.2. *Being free is an open. Hence $\text{Hom}^{\text{free}}(\mathbb{P}^1, X) \subset \text{Hom}(\mathbb{P}^1, X)$ is open.*

Proof. Trivial by definition. \square

Theorem 1.3.3. *Let C be a proper curve and X a smooth variety. Let $B \subset C$ be a closed subscheme with ideal sheaf \mathcal{I}_B and $g = f|_B$. Let $F : C \times \text{Hom}(C, X; g) \rightarrow X$ be the universal morphism. Then $T_{\kappa(p, [f]), C \times \text{Hom}(C, X; g)} = T_{\kappa(p), C} \oplus H^0(C, f^*T_X \otimes \mathcal{I}_B)$ if $p \notin B$. Consider the differential $df(s) : T_{\kappa(s), C} \rightarrow T_{\kappa(f(s)), X}$ and evaluation map*

$$\phi(p, f) : H^0(C, f^*T_X \otimes \mathcal{I}_B) \rightarrow f^*T_X \otimes \kappa(p),$$

then $dF(p, [f]) = df(p) + \phi(p, f)$. Furthermore If $\phi(p, f)$ is surjective, then F is smooth at $(p, [f])$. The converse also holds if $H^0(T_C \otimes \mathcal{I}_B) \rightarrow T_{\kappa(p), C}$ is surjective.

Proof. Trivial by definitions. \square

Corollary 1.3.4. *If C is smooth and $f : C \rightarrow X$ is free over g , then $F : C \times \mathrm{Hom}(C, X; g) \rightarrow X$ is smooth along $(C \setminus B) \times [f]$. In particular $\mathbb{P}^1 \times \mathrm{Hom}^{\mathrm{free}}(\mathbb{P}^1, X) \rightarrow X$ is smooth.*

Proposition 1.3.5. *Assume that $f : \mathbb{P}^1 \rightarrow X$, $g = f|_B$, $\mathrm{length} B \leq 2$ and write $f^*T_X \otimes \mathcal{I}_B = \sum_i \mathcal{O}(a_i)$. Then $\#\{i : a_i \geq 0\} = \mathrm{rank} dF(p, [f])$ for all $p \in \mathbb{P}^1 \setminus B$.*

In particular, if

$$F_{\mathrm{red}} : \mathbb{P}^1 \times \mathrm{Hom}(\mathbb{P}^1, X; g)_{\mathrm{red}} \rightarrow X$$

is smooth at $(p, [f])$ for some $p \in \mathbb{P}^1$, then f is free over g .

Proof. Note that $\mathrm{length} B \leq 2$ implies $H^0(T_{\mathbb{P}^1} \otimes \mathcal{I}_B) \rightarrow T_{\kappa(p), \mathbb{P}^1}$ is surjective for all $p \in \mathbb{P}^1 \setminus B$. Then these are trivial by arguments in Theorem 1.3.3. \square

Theorem 1.3.6 (Kollár-Miyaoka-Mori, 1992). *Let X be a smooth projective variety over k . Let $B \subset \mathbb{P}_k^1$ be a closed subscheme with $\mathrm{length} B \leq 2$ and $g : B \rightarrow X$. There are countably many subvarieties $V_i = V_i(B, g) \subset X$ such that if $f : \mathbb{P}^1 \rightarrow X$ is a nonconstant morphism such that $f|_B = g$ and $\mathrm{Im}(f) \not\subseteq \bigcup_i V_i$, then f is free over B .*

Proof. Let Z_i be the irreducible components of $\mathrm{Hom}(\mathbb{P}^1, X; g)$ with universal morphisms $F_i : \mathbb{P}^1 \times Z_i \rightarrow X$. Let $V_i = \overline{\mathrm{Im}(F_i)}$ if F_i is not dominant, and $V_i = X \setminus U_{F_i}$ if F_i is dominant, where $U_{F_i} \subset X$ is an open and dense subset such that $F_{i, \mathrm{red}} : \mathbb{P}^1 \times Z_{i, \mathrm{red}} \rightarrow X$ is smooth over U_{F_i} (this is where we use the $\mathrm{char} = 0$ assumption). Then the result is trivial. \square

Theorem 1.3.7. *Let X be a smooth proper variety over k , then the following statements are equivalent.*

- (1) X is uniruled.
- (2) Generic rational curves of X are free.
- (3) X has a free rational curve.

Proof. If X is uniruled then since the morphism

$$F_{\mathrm{red}} : \mathbb{P}^1 \times \mathrm{Hom}(\mathbb{P}^1, X; g)_{\mathrm{red}} \rightarrow X$$

is dominant, it is generic smooth. Hence by Proposition 1.3.5 the generic rational curves of X are free.

If the generic rational curves of X are free, then X has a free rational curve.

If X has a free rational curve, then the morphism $\mathbb{P}^1 \times \mathrm{Hom}^{\mathrm{free}}(\mathbb{P}^1, X) \rightarrow X$ is smooth by Corollary 1.3.4. Hence it has dense image. Hence X is uniruled. \square

Remark 1.3.8. *More properties of uniruled varieties we refer Section IV.1 in [15].*

1.3.2 Minimal Rational Curves

Definition 1.3.9. Let X be a smooth projective variety over k of dimension n .

(a) A rational curve $f : \mathbb{P}^1 \rightarrow X$ is called **standard** if

$$f^*T_X \cong \mathcal{O}_{\mathbb{P}^1}(2) \oplus \mathcal{O}_{\mathbb{P}^1}(1)^{\oplus p} \oplus \mathcal{O}_{\mathbb{P}^1}^{\oplus n-1-p}$$

where $p + 2 = -\deg f^*K_X$.

(b) Let X be a smooth Fano variety over k . A morphism $f : \mathbb{P}^1 \rightarrow X$ is called a **minimal free rational curve** if it is a free rational curve such that $-\deg f^*K_X$ is minimal.

(c) Let X be a smooth Fano variety over k . A morphism $f : \mathbb{P}^1 \rightarrow X$ is called a **minimal rational curve** if it is a deformation of the minimal free rational curves. An irreducible component $\mathcal{K} \subset \text{RatCurves}^n(X)$ is called a **minimal rational component** if it contains a rational curve of minimal degree.

Remark 1.3.10. For any non-constant $f : \mathbb{P}^1 \rightarrow X$, it can be factored by $f : \mathbb{P}^1 \xrightarrow{g} \mathbb{P}^1 \xrightarrow{h} X$ where h is birational to its image, then it is a immersion at generic points. Hence $T_{\mathbb{P}^1} = \mathcal{O}_{\mathbb{P}^1}(2) \subset h^*T_X$. Hence $\mathcal{O}_{\mathbb{P}^1}(2 \deg g) \subset f^*T_X$. So if we let $f^*T_X \cong \mathcal{O}_{\mathbb{P}^1}(a_1) \oplus \cdots \mathcal{O}_{\mathbb{P}^1}(a_n)$ with $a_1 \geq \cdots \geq a_n$, then $a_1 \geq 2$.

Proposition 1.3.11. Let X be a smooth proper variety over k .

- (a) If X has a free rational curve, then generic free rational curves of X are standard.
- (b) If X is Fano and $x \in X$ is a general point, let minimal rational component $\mathcal{K} \subset \text{RatCurves}^n(X)$ and the corresponding component $\mathcal{K}_x \subset \text{RatCurves}_{p+2}^n(x, X)$ be of minimal degree $p + 2$. Then \mathcal{K}_x is a union of smooth varieties of dimension p and the general points are minimal standard.

Proof. For (a), let that free rational curve is g , pick an irreducible component $V \subset \text{Hom}_{\text{bir}}(\mathbb{P}^1, X)$ containing $[g]$. Then by Theorem 1.3.7 V is dominated to X . Then by Theorem IV.2.4 and Corollary IV.2.9 in [15] there is a $W \subset \text{Hom}_{\text{bir}}(\mathbb{P}^1, X)$ such that dominated to X and general points in W is standard.

For (b), WLOG we let \mathcal{K}_x irreducible and let $V \subset \text{Hom}_{\text{bir}}^n(\mathbb{P}^1, X; 0 \mapsto x)$ be the irreducible component correspond to \mathcal{K}_x . Now since x is general, by Theorem 1.3.6 any members of V and hence \mathcal{K}_x are free. Hence for any $[f] \in V$ we have $H^1(\mathbb{P}^1, f^*T_X \otimes \mathfrak{m}_0) = 0$. Then $\text{Hom}_{\text{bir}}^n(\mathbb{P}^1, X; 0 \mapsto x) = \text{Hom}_{\text{bir}}(\mathbb{P}^1, X; 0 \mapsto x)$ is smooth at $[f]$ in this case. Hence by Theorem 1.1.21 V is also smooth at $[f]$ and of dimension $H^0(\mathbb{P}^1, f^*T_X \otimes \mathfrak{m}_0) = p + 2$. Hence by Theorem 1.2.8(b) the morphism $u : \text{Hom}_{\text{bir}}^n(\mathbb{P}^1, X; 0 \mapsto x) \rightarrow \text{RatCurves}^n(x, X)$ is smooth and is an $\text{Aut}(\mathbb{P}^1; 0)$ -bundle, hence so is $V \rightarrow \mathcal{K}_x$. So \mathcal{K}_x is smooth variety of dimension p . \square

1.4 Bend and Break

Bend and Break is a classical method aiming to find the rational curves over the projective varieties which is first observed by S. Mori in [19]. Here we will give the main results proved in [15]. See also the first chapter in [14] for a brief introduction. Here we assume all schemes over a infinity field k .

1.4.1 Main Results of Bend and Break

Definition 1.4.1. Let S be a proper surface and $B \subset S$ a proper curve. We say that B is *contractible in S* if there is a surface S' and a dominant morphism $g : S \rightarrow S'$ such that $g(B)$ is zero dimensional.

Proposition 1.4.2 (Rigidity Lemma). Let $f : X \rightarrow Y$ be a proper morphism such that $f_*\mathcal{O}_X = \mathcal{O}_Y$. Let $g : X \rightarrow Z$ be a morphism. Assume that for some $y \in Y$ there is a factorization

$$\begin{array}{ccc}
 & & Z \\
 & \nearrow g & \\
 X & \xleftarrow{f^{-1}(y)} & g|_{f^{-1}(y)} \\
 \downarrow f & & \downarrow f_y \\
 Y & \xleftarrow{\quad} & \{y\}
 \end{array}
 \quad \begin{array}{c} \\ \\ \\ \nearrow h_y \end{array}$$

Then there is an open neighborhood $y \in U \subset Y$ and a factorization

$$\begin{array}{ccc}
 & & Z \\
 & \nearrow g & \\
 X & \xleftarrow{f^{-1}(U)} & g|_{f^{-1}(U)} \\
 \downarrow f & & \downarrow f_U \\
 Y & \xleftarrow{\quad} & U
 \end{array}
 \quad \begin{array}{c} \\ \\ \\ \nearrow h_U \end{array}$$

Proof. Let $\Gamma \subset Y \times Z$ be the image of (f, g) . Then $p : \Gamma \rightarrow Y$ is proper and $p^{-1}(y) = (y, h_y(y))$ is finite over y . Thus there is an open neighborhood $y \in U \subset Y$ such that $p^{-1}(U) \rightarrow U$ is finite. Since

$$f_*\mathcal{O}_{f^{-1}(U)} \supset p_*\mathcal{O}_{p^{-1}(U)} \supset \mathcal{O}_U \supset f_*\mathcal{O}_{f^{-1}(U)}$$

which shows that $p^{-1}(U) \rightarrow U$ is an isomorphism. \square

Corollary 1.4.3. Let S be a proper surface and $B \subset S$ a contractible curve. Then $B \cdot B < 0$.

In particular, let D be an irreducible and proper curve and C an arbitrary curve. Let $B_c = B \times \{c\} \subset B \times C$ where $c \in C$ is arbitrary. Then B_c is not contractible in $B \times C$.

Proof. Since $B \subset S$ is contractible, there is a surface S' and a dominant morphism $g : S \rightarrow S'$ such that $g(B)$ is zero dimensional. We prove this only for S smooth and S' projective. The general case works the same once the definition of intersection numbers is established in general.

Since S' projective, then we can find a finite morphism $f : S' \rightarrow \mathbb{P}^2$ since k is infinity. Let $\mathcal{O}(H) = f^*\mathcal{O}(1)$ which is ample and $H \cdot H > 0$ and $H \cdot B = 0$. By Hodge index theorem we have $B \cdot B < 0$.

For the final statement, note that $B_c \cdot B_c = 0$ hence B_c is not contractible. \square

Theorem 1.4.4 (Fundamental Bend and Break, Mori-Miyaoka 1979-1986). *Let B be a smooth proper and irreducible curve over k and S an irreducible, proper and normal surface. Let $p : S \rightarrow B$ be a morphism. Assume that there is an open subset $B^0 \subset B$, a smooth projective curve C and an isomorphism*

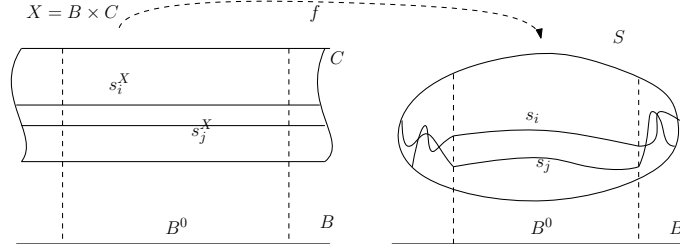

$$f : [C \times B^0 \xrightarrow{\pi} B^0] \cong [p^{-1}(B^0) \xrightarrow{p} B^0].$$

We call a section $s : B \rightarrow S$ is called flat if $s(B^0) = \{c\} \times B^0$ under the above isomorphism.

- (a) If there is a contractible flat section $s_1 : B \rightarrow S$, then for some $b \in B \setminus B^0$ the fiber $p^{-1}(b)$ contains a rational curve intersecting $s_1(B)$.
- (b) If k algebraically closed, $g(C) = 0$ and there are two contractible sections $s_1, s_2 : B \rightarrow S$, then for some $b \in B \setminus B^0$ the fiber $p^{-1}(b)$ is either reducible or nonreduced.
- (c) Let L be a nef \mathbb{R} -Cartier divisor on S . If there are $k \geq 1$ contractible flat sections $s_i : B \rightarrow S$ such that $L \cdot s_i(B) = 0$ for every i , then for some $b \in B \setminus B^0$ the fiber $p^{-1}(b)$ contains a rational curve D intersecting a section $s_i(B)$ such that $L \cdot D \leq \frac{2}{k} L \cdot C$ where C be the general fiber of p .
- (d) Let L be a nef \mathbb{R} -Cartier divisor on S with $L^2 > 0$. If there are k contractible flat sections $s_i : B \rightarrow S$ such that $L \cdot s_i(B) = 0$ for every i , then for some $b \in B \setminus B^0$ the fiber $p^{-1}(b)$ contains a rational curve D intersecting a section $s_i(B)$ such that $0 < L \cdot D < \frac{2}{k} L \cdot C$ where C be the general fiber of p .

Proof. Let $X := C \times B$ and $\Gamma \subset X \times_B S$ be the closure of the graph of f . Consider projections p_X, p_S and every flat section s_i induces a flat section $s_i^X : B \rightarrow X$:

By Corollary 1.4.3 the rational map $f : X \dashrightarrow S$ is not defined some where along $s_i^X(B)$ if s_i contractible. Here we only prove (a) and (b). Actually (c) and (d) including the same idea with complicated computation and we refer Theorem II.5.4 in [15].

For (a), since $s_1 : B \rightarrow S$ is a contractible flat section, then $f : X \dashrightarrow S$ is not defined some where along $s_1^X(B)$. So we have a exceptional curve $D' \subset \Gamma$ of p_X . One can show that D' is rational, then take $D = p_S(D')$ and we get (a).

For (b), we assume that every fibres of p are integral, then $h^1(\mathcal{O}_{p^{-1}(b)}) = 1 - \chi(\mathcal{O}_{p^{-1}(b)})$ since k is algebraically closed. Then it is independent of $b \in B$ and every fiber of p is isomorphic to \mathbb{P}^1 . Since p has sections, then S is a minimal ruled surface over B . Now the matrix of intersection form of $s_1(B), s_2(B)$ and $C \times \{b\}$ is $\mathbf{M} = \begin{pmatrix} -a_1 & c & 1 \\ c & -a_2 & 1 \\ 1 & 1 & 0 \end{pmatrix}$ where $-a_i = s_i(B)^2 < 0$ by Corollary 1.4.3 and $c = s_1(B) \cdot s_2(B) \geq 0$.

Hence $\det \mathbf{M} = 2c + a_1a + 2 > 0$ which is impossible since $\dim N_1(S) = 2$ since $N_1(S)$ generated by $s_1(B)$ and $C \times \{b\}$. \square

Corollary 1.4.5. *Let C be an irreducible, proper and smooth curve and X a proper variety. Let $p_1, \dots, p_k \in C$ be k distinct points and $g : \{p_1, \dots, p_k\} \rightarrow X$ a morphism. Assume that there is a smooth, irreducible, proper curve B , an open set $B^0 \subset B$ and a morphism*

$$[h^0 : C \times B^0 \rightarrow X \times B^0] \in \text{Hom}(C, X; g)(B^0)$$

such that $h^0(C \times \{b\})$ and $p_X \circ h^0(\{c\} \times B^0)$ are one dimensional for some $b \in B^0$ and $c \in C$.

Then there is a unique normal compactification $S \supset C \times B^0$ such that h^0 extends to a finite morphism $h : S \rightarrow X \times B$. Let $p : S \rightarrow B$.

- (a) *If $k \geq 1$, then for some $b \in B \setminus B^0$ the 1-cycle $h_*(p^{-1}(b))$ contains a rational curve D which passes through $g(p_1)$.*
- (b) *If $C \cong \mathbb{P}^1$, $\dim \text{Im}(p_X \circ h^0) = 2$ and $k \geq 2$, then for some $b \in B \setminus B^0$ the 1-cycle $h_*(p^{-1}(b))$ is either reducible or nonreduced.*
- (c) *Let L be a nef \mathbb{R} -Cartier divisor on X and $k \geq 1$. Then for some $b \in B \setminus B^0$ the 1-cycle $h_*(p^{-1}(b))$ contains a rational curve D such that $0 \leq L \cdot D \leq \frac{2}{k} L \cdot h_* C$ and $\{g(p_1), \dots, g(p_k)\} \cap D \neq \emptyset$.*

- (d) Let L be a nef \mathbb{R} -Cartier divisor on X with $h^*L^2 > 0$ and $k \geq 1$. Then for some $b \in B \setminus B^0$ the 1-cycle $h_*(p^{-1}(b))$ contains a rational curve D such that $0 < L \cdot D < \frac{2}{k}L \cdot h_*C$ and $\{g(p_1), \dots, g(p_k)\} \cap D \neq \emptyset$.

Proof. If $h^0(C \times \{b\})$ is a point for some $b \in B^0$, then by rigidity lemma $h^0(C \times \{b\})$ is a point for any $b \in B^0$, a contradiction. Thus h^0 is finite on every fiber of $C \times B^0 \rightarrow B^0$, hence the natural morphism h^0 is quasifinite. $S \supset C \times B^0$ such that h^0 extends to a finite morphism $h : S \rightarrow X \times B$.

If $\text{Im}(p_X \circ h^0)$ is of dimension one, this is not hard to see. If $\text{Im}(p_X \circ h^0)$ is of dimension two, then any p_i determines a contractible flat section of S given by $s_i : B^0 \rightarrow \{p_i\} \times B^0$. Then this follows from Theorem 1.4.4. \square

Theorem 1.4.6 (Bend and Break). *Let C be an irreducible, proper and smooth curve and X a proper variety. Let $f : C \rightarrow X$ be a nonconstant morphism.*

- (a) *If $\dim_{[f]} \text{Hom}(C, X) \geq \dim X + 1$, then for every $x \in f(C)$ there is a morphism $f_x : C \rightarrow X$ and a 1-cycle $\sum_i a_i D_i$ whose irreducible components are rational curves such that $x \in \text{supp}(\sum_i a_i D_i)$ and*

$$f_*[C] \sim_{\text{alg}} (f_x)_*[C] + \sum_i a_i [D_i].$$

- (b) *If $g(C) = 0$ and $\dim_{[f]} \text{Hom}(C, X) \geq 2 \dim X + 2$ (holds if $-K_X \cdot C \geq n + 2$), then for every $x_1, x_2 \in f(C)$ there is a 1-cycle $\sum_i a_i D_i$ whose irreducible components are rational curves such that $x_1, x_2 \in \text{supp}(\sum_i a_i D_i)$ and*

$$f_*[C] \sim_{\text{alg}} \sum_i a_i [D_i], \quad \sum_i a_i \geq 2.$$

- (c) *Let L be a nef \mathbb{R} -Cartier divisor on X and $k \geq 1$. If $\dim_{[f]} \text{Hom}(C, X) \geq k \dim X + 1$, then for every $x \in f(C)$ there is a morphism $f_x : C \rightarrow X$ and a 1-cycle $\sum_i a_i D_i$ ($a_1 > 0$) whose irreducible components are rational curves such that $x \in D_1$ and*

$$f_*[C] \sim_{\text{alg}} (f_x)_*[C] + \sum_i a_i [D_i], \quad L \cdot D_1 \leq \frac{2}{k}L \cdot f_*C.$$

Proof. Choose $\{p_1, \dots, p_k\} \subset C$ with $g = f|_{\{p_1, \dots, p_k\}}$, then by Proposition 1.1.19 we have

$$\dim_{[f]} \text{Hom}(C, X; g) \geq \dim_{[f]} \text{Hom}(C, X) - k \dim X.$$

For (a), we assume $k = 1$ and $f(p_1) = x$ then $\dim_{[f]} \text{Hom}(C, X; g) \geq 1$. Let B^0 be the normalization of an irreducible curve in $\text{Hom}(C, X; g)$ containing $[f]$ and $h^0 : C \times B^0 \rightarrow$

$X \times B^0$ the natural cycle morphism. By Corollary 1.4.5 we have compactifications B and S . Resolve the indeterminacies of $C \times B \dashrightarrow S$ we get

$$\begin{array}{ccccc} C \times B & \xleftarrow{\rho_X} & Y & \xrightarrow{\rho_S} & S & \xrightarrow{h} & X \times B \\ & \searrow q & & \swarrow p & & & \\ & & B & & & & \end{array}$$

Pick $b \in B \setminus B^0$ as before we get $(p \circ \rho_S)^{-1}(b) = (q \circ \rho_X)^{-1}(b) = [C_0] + \sum_j e_j[E_j]$ where $C_0 \cong C$ and E_j rational as the exceptional curves of ρ_X . Set $f_x = (h \circ \rho_S)|_{C_0}$ and $\sum_i a_i D_i = (h \circ \rho_S)_*(\sum_j e_j[E_j])$ and well done.

The proof of (b) is similar as (a) using Corollary 1.4.5(b).

For (c), as before we obtain $D = D_1$ which satisfies all the requirements except that we only know that $D \cap \{f(p_1), \dots, f(p_k)\} \neq \emptyset$. By letting the points p_i vary, we conclude that (c) holds except possibly for $k - 1$ points of $f(C)$.

Let $W \subset \text{Chow}^1(X)$ be the connected component of $f_*[C]$. Let $V \subset W$ be the set of those points such that the corresponding cycle Z has the form $Z \sim_{\text{alg}} (f_x)_*[C] + \sum_i a_i[D_i]$ where the D_i are rational. By Proposition 1.2.1 V is closed in W and hence proper. By Corollary 1.2.2 $\text{RatLocus}(V) \subset X$ is closed. Thus $\text{RatLocus}(V) \cap C$ is a closed subset whose complement has at most $k - 1$ points. Therefore $C \subset \text{RatLocus}(V)$ and this completes the proof. \square

Theorem 1.4.7 (Smooth Bend and Break, Mori 1979-1982). *Let X be a smooth projective variety.*

- (a) *Let $f : \mathbb{P}^1 \rightarrow X$ be a nonconstant morphism. Then for every $x \in f(\mathbb{P}^1)$ there is a 1-cycle $\sum_i a_i D_i$ whose irreducible components are rational curves such that $x \in \text{supp}(\sum_i a_i D_i)$ and*

$$f_*[C] \sim_{\text{alg}} \sum_i a_i [D_i], \quad -K_X \cdot D_i \leq \dim X + 1.$$

- (b) *Let C be a smooth, projective and irreducible curve and $f : C \rightarrow X$ a morphism. Assume that $\deg_C f^*(-K_X) > g(C) \dim X$, then for every $x \in f(C)$ there is a morphism $f_x : C \rightarrow X$ and a 1-cycle $\sum_i a_i D_i$ whose irreducible components are rational curves such that $x \in \text{supp}(\sum_i a_i D_i)$ and $\deg_C f_x^*(-K_X) \leq g(C) \dim X$ and*

$$f_*[C] \sim_{\text{alg}} (f_x)_*[C] + \sum_i a_i [D_i], \quad -K_X \cdot D_i \leq \dim X + 1.$$

Proof. By using Theorem 1.4.6(b) to our (a) and 1.4.6(a) to our (b) and induction on $\deg f^*H$ for some fixed ample divisor H on X , we can get the results. \square

1.4.2 Connection of Zero and Positive Characteristics

When we want to find the rational curves on variety X , we need to use the bend and break as Theorem 1.4.6(c). For any $f : C \rightarrow X$ passing $x \in X$ we need to make sure that $\dim_{[f]} \operatorname{Hom}(C, X) \geq k \dim X + 1$ for some k . Now by Theorem 1.1.18 we have

$$\dim_{[f]} \operatorname{Hom}(C, Y) \geq -C \cdot K_Y + \dim X \chi(\mathcal{O}_C) = -C \cdot K_Y + \dim X - \dim X g(C).$$

If $-K_X \cdot C > 0$, to make sure the latter number larger, we need to find $C' \rightarrow C$ such that $-K_X \cdot C'$ larger but $g(C)$ do not change.

For $g(C) = 0$ we can use the large degree map $\mathbb{P}^1 \rightarrow \mathbb{P}^1$; for $g(C) = 1$ we use the $\times n$ morphism. But if $g(C) \geq 2$ we do not have such things. Now that in $\operatorname{char} = p$ case we have Frobenius map which satisfies this condition. So we need to make $\operatorname{char} = 0$ into $\operatorname{char} = p$ case and come back to $\operatorname{char} = 0$. This is the magic method due to Mori.

Assume that we are given finitely many schemes of finite type X_i , coherent sheaves \mathcal{F}_i and maps g_i defined over a field k . All of these can be described by a finite number of equations (the schemes are given by affine charts and patching functions, the sheaves by finitely presented modules over the affine charts and patchings and the maps are described by their graphs which are schemes themselves). All these equations involve only finitely many elements a_j of the field k .

Let $\mathbb{F} \subset k$ be a subring which denote \mathbb{F}_p if $\operatorname{char}(k) = p$ and \mathbb{Z} if $\operatorname{char}(k) = 0$. Let $R := \mathbb{F}[a_j]$ is a finite type \mathbb{F} -algebra.

Lemma 1.4.8. *Let R be a finitely generated ring over \mathbb{F} . Then*

- (a) *The residue field R/\mathfrak{m} of any maximal ideal $\mathfrak{m} \subset R$ is finite.*
- (b) *The maximal ideals are dense in $\operatorname{Spec} R$.*

Proof. (a) is trivial and (b) follows from both cases are Jacobson rings. \square

Aftering choose a_j and then R , we may consider X_i , \mathcal{F}_i and g_i defined over $\operatorname{Spec} R$ which we denote them as X_i^R, \mathcal{F}_i^R and g_i^R . Hence after base change to $\operatorname{Spec} k$ we again have X_i, \mathcal{F}_i, g_i . Hence we constructed data $\{X_i^R, \mathcal{F}_i^R, g_i^R\}$ over $\operatorname{Spec} R$ such that the fibers over $\operatorname{Spec} k$ are the original data $\{X_i, \mathcal{F}_i, g_i\}$. Similarly for maximal ideal $\mathfrak{m} \subset R$ we have data $\{X_i^{\mathfrak{m}}, \mathcal{F}_i^{\mathfrak{m}}, g_i^{\mathfrak{m}}\}$ over $\operatorname{Spec} R/\mathfrak{m}$ which is positive characteristic by the previous Lemma (a).

Definition 1.4.9. *Let (P) be a property of schemes (morphisms etc.) in algebraic geometry. We say that (P) is of finite type if:*

Let K/k be a field extension and X_k a k -scheme. Then (P) holds for X_K iff there is a finitely generated subextension $K/F/k$ such that (P) holds for X_L for every L/F .

Remark 1.4.10. *A typical property that is not of finite type is: X_K has only finitely many K -points.*

Theorem 1.4.11 (Meta). *Let $(P_1) \Rightarrow (P_2)$ be a statement in algebraic geometry that we want to prove. Assume the following four conditions:*

- (1) (P_1) and (P_2) are of finite type.
- (2) If (P_1) holds for the generic fiber of a morphism $X \rightarrow Y$, then it holds for every fiber over a nonempty open set.
- (3) If (P_2) holds for every fiber of a morphism $X \rightarrow Y$ over a (not necessarily open) dense set, then it holds for the generic fiber.
- (4) $(P_1) \Rightarrow (P_2)$ holds in positive characteristic.

Then $(P_1) \Rightarrow (P_2)$ always holds.

We may not use this meta-theorem and we will show how to use the proccess before the theorem, that is, a proof of the special (but nice and classical) case of the theorem in the next section.

1.4.3 Applications of General Varieties and Fano Varieties

We assume that all varieties over an algebraically closed field k .

Theorem 1.4.12 (Kollár-Miyaoka-Mori, 1979-1982-1986-1991). *Let X be a projective variety over k , let C a smooth, projective and irreducible curve, $f : C \rightarrow X$ a morphism and M any nef \mathbb{R} -divisor. Assume that X is smooth along $f(C)$ and $-K_X \cdot C > 0$.*

Then for every $x \in f(C)$ there is a rational curve $L_x \subset X$ containing x such that

$$M \cdot L_x \leq 2 \dim X \frac{M \cdot C}{-K_X \cdot C}.$$

Proof. Fix the condition in the theorem and consider the following proposition:

- (P) M any ample \mathbb{R} -divisor and $\varepsilon > 0$ there is a rational curve $L_{x,\varepsilon} \subset X$ containing x such that

$$M \cdot L_{x,\varepsilon} \leq (2 \dim X + \varepsilon) \frac{M \cdot C}{-K_X \cdot C}.$$

Now we prove this theorem with several steps:

► **Step 1.** Prove the proposition (P) for M is ample divisor and $\text{char} = p > 0$.

Consider the Frobenius $F^m : C^m \rightarrow C$ of degree p^m and consider $f^m : C^m \rightarrow X$, then $-K_X \cdot C^m = p^m(-K_X \cdot C)$. Hence by Theorem 1.1.18 we have

$$\dim_{[f^m]} \text{Hom}(C^m, X) \geq p^m(-K_X \cdot C) + \dim X \chi(\mathcal{O}_C)$$

since X is smooth along $f(C)$. Then for $m \gg 0$ we have $\dim_{[f^m]} \text{Hom}(C^m, X) \geq p^m \frac{-K_X \cdot C}{\dim X + \varepsilon/2} \dim X + 2$. By Theorem 1.4.6(c) and we get the claim.

► **Step 2.** Prove the proposition (P) for $\text{char} = 0$.

We just need to show the case when M is ample divisor since \mathbb{R} -divisor can be approximated by \mathbb{Q} -divisors.

Let $f(p) = x$ and we construct R as before such that $p \in C \xrightarrow{f} X$ and M over $\text{Spec } R$. Hence we have $p^R, x^R, C^R, f^R, X^R, M^R$. By shrinking $\text{Spec } R$ we may assume $C^R \rightarrow \text{Spec } R$ is smooth, $X^R \rightarrow \text{Spec } R$ is smooth along $f^R(C^R)$ and M^R is locally free (since $K(R)$ is of $\text{char} = 0$).

Let $W_\varepsilon \subset \text{Chow}^1(X_R/\text{Spec } R)$ be the subvariety parametrizing those 1-cycles $Z = \sum_i a_i D_i$ which satisfies that every D_i is rational and $Z \cdot M \leq (2 \dim X + \varepsilon) \frac{M \cdot C}{-K_X \cdot C}$ and $\text{supp}(Z) \cap f^R(X^R) \neq \emptyset$. Consider $\pi : W_\varepsilon \rightarrow \text{Spec } R$. We claim that π is surjective.

Indeed, we know that π is proper by Theorem 1.1.15 and Proposition 1.2.1. Since the closed points dense in $\text{Spec } R$, we just need to show that $\pi(W_\varepsilon)$ contains all closed points of $\text{Spec } R$. Pick a maximal ideal $\mathfrak{m} \subset R$ and $\{p^\mathfrak{m}, x^\mathfrak{m}, C^\mathfrak{m}, f^\mathfrak{m}, X^\mathfrak{m}, M^\mathfrak{m}\}$ as before over $\text{Spec } R/\mathfrak{m}$ of positive characteristic. Hence by Step 1 we have rational curve $L_{x^\mathfrak{m}, \varepsilon}$ such that $[L_{x^\mathfrak{m}, \varepsilon}] \in W_\varepsilon$. Hence we get the claim.

By the claim we find that $W_\varepsilon \times_{\text{Spec } R} \text{Spec } k \neq \emptyset$. Hence we finish this step.

► **Step 3.** Prove the theorem.

Now come back to our general theorem. Now M be any nef \mathbb{R} -divisor and we fix an ample divisor H . Then $kM + H$ is ample for any $k \geq 0$. By Step 1,2, for any $\varepsilon > 0$ there is a rational curve $L_{x,k,\varepsilon} \subset X$ containing x such that

$$(kM + H) \cdot L_{x,k,\varepsilon} \leq (2 \dim X + \varepsilon) k \frac{M \cdot C}{-K_X \cdot C} + (2 \dim X + \varepsilon) \frac{H \cdot C}{-K_X \cdot C}.$$

Then we have

$$k \left(M \cdot L_{x,k,\varepsilon} - 2 \dim X \frac{M \cdot C}{-K_X \cdot C} \right) + H \cdot L_{x,k,\varepsilon} \leq (2 \dim X + \varepsilon) \frac{H \cdot C}{-K_X \cdot C} + k\varepsilon \frac{M \cdot C}{-K_X \cdot C}.$$

If $M \cdot L_{x,k_0,\varepsilon} - 2 \dim X \frac{M \cdot C}{-K_X \cdot C} \leq 0$ for some k_0, ε , then we take $L_x := L_{x,k_0,\varepsilon}$ and then well done. If not we have

$$H \cdot L_{x,k,\varepsilon} \leq (2 \dim X + \varepsilon) \frac{H \cdot C}{-K_X \cdot C} + k\varepsilon \frac{M \cdot C}{-K_X \cdot C}.$$

for every k, ε . Set $\varepsilon = \frac{1}{k}$ and $k \rightarrow \infty$. We obtain a sequence of curves $L_{x,k} := L_{x,k,1/k}$. So $H \cdot L_{x,k}$ is uniformly bounded, thus the $L_{x,k}$ form a bounded family. By Theorem 1.1.15 $\text{Chow}^1(X)$ has only finitely many components parametrizing 1-cycles of bounded degree. In particular there is a subsequence $k_i \rightarrow \infty$ such that $P := P(i) := M \cdot L_{x,k_i} - 2 \dim X \frac{M \cdot C}{-K_X \cdot C}$ is independent of i . Hence

$$k_i P \leq (2 \dim X + 1) \frac{H \cdot C}{-K_X \cdot C} + \varepsilon \frac{M \cdot C}{-K_X \cdot C}, \quad k_i \rightarrow \infty.$$

Hence $P \leq 0$ and we take $L_x := L_{x,k_i}$ and well done. \square

Theorem 1.4.13 (Smooth Case). *Let X be a smooth projective variety, C a smooth, projective and irreducible curve and $f : C \rightarrow X$ a morphism. Let M be any nef \mathbb{R} -divisor. Assume that $-K_X \cdot C > 0$, then for any $x \in f(C)$ there is a rational curve $D_x \subset X$ containing x such that*

$$M \cdot D_x \leq 2 \dim X \frac{M \cdot C}{-K_X \cdot C}, \quad -K_X \cdot D_x \leq \dim X + 1.$$

Proof. Use Theorem 1.4.7 and Theorem 1.4.12. This is trivial. \square

Remark 1.4.14. *Both Theorem 1.4.12 and Theorem 1.4.13 have generalizations with the same proof, see Theorem II.1.3 and Remark II.5.15 in [15].*

Corollary 1.4.15 (Fano Case). *Let X be a smooth Fano variety, then for any x there is a rational curve $D_x \subset X$ containing x such that $-K_X \cdot D_x \leq \dim X + 1$. In particular any smooth Fano variety is uniruled.*

1.5 Application I: Basic Theory of Fano Manifolds

Some general theory of Fano varieties we refer [21]. Here we give some important basic theory of Fano manifolds. We consider any schemes over an algebraically closed field k .

1.5.1 Some General Properties

Theorem 1.5.1. *Let G be a reduced and connected linear algebraic group and X be a proper homogeneous space under the action of G . Pick $x \in X$ and stabilizer $G_x \subset G$. If G_x is reduced (always hold if $\text{char} = 0$), then T_X is generated by global sections and $-K_X$ is very ample.*

Proof. Omitted, we refer Theorem V.1.4 in [15]. \square

Proposition 1.5.2. *Let X be a smooth Fano variety over an algebraically closed field k of characteristic zero.*

(a) *We have $\chi(X, \mathcal{O}_X) = 1$ and X is simply connected.*

(b) *$\text{Pic}(X)$ is finite generated and torsion free.*

Proof. For (a), by Kodaira's vanishing theorem we find that $H^m(X, \mathcal{O}_X) = 0$ for all $m > 0$, hence $\chi(X, \mathcal{O}_X) = 1$. If $\pi : X' \rightarrow X$ is a connected finite étale cover, then X is also a smooth Fano variety. Hence $\chi(X', \mathcal{O}_{X'}) = 1$. But $\chi(X', \mathcal{O}_{X'}) = \deg \pi \chi(X, \mathcal{O}_X)$. Hence π is an isomorphism.

For (b) we may assume $k = \mathbb{C}$. By exponential sequence one has

$$H^1(X, \mathcal{O}_X) \rightarrow \text{Pic}(X) \rightarrow H^2(X, \mathbb{Z}) \rightarrow H^2(X, \mathcal{O}_X).$$

By Kodaira's vanishing theorem, we find that $H^m(X, \mathcal{O}_X) = 0$ for all $m > 0$, hence $\text{Pic}(X) \cong H^2(X, \mathbb{Z})$. Hence $\text{Pic}(X)$ is finite generated. To show $\text{Pic}(X)$ is torsion free, we just need to show $H^2(X, \mathbb{Z})$ is torsion free. By universal coefficient theorem for cohomology, one has

$$0 \rightarrow \text{Ext}^1(H_1(X, \mathbb{Z}), \mathbb{Z}) \rightarrow H^2(X, \mathbb{Z}) \rightarrow \text{Hom}(H_2(X, \mathbb{Z}), \mathbb{Z}) \rightarrow 0.$$

As $\text{Hom}(H_2(X, \mathbb{Z}), \mathbb{Z})$ is torsion free, the only torsion of $H^2(X, \mathbb{Z})$ follows from $H_1(X, \mathbb{Z})$. As $H_1(X, \mathbb{Z}) = \pi_1(X)^{\text{abel}} = 0$ by (a), hence $\text{Pic}(X)$ is torsion free. \square

Theorem 1.5.3 (Cone Theorem). *Let X be a smooth Fano variety over an algebraically closed field k . On X there are only finitely many families of rational curves C_μ such that $-K_X \cdot C_\mu \leq \dim X + 1$. Let $C_i : 1 \leq i \leq N$ be a set of representatives, then*

$$\overline{\text{NE}}(X) = \text{NE}(X) = \sum_i \mathbb{R}^+[C_i].$$

Proof. A very special case of Theorem 3.7 in [14]. Omitted. \square

Proposition 1.5.4. *Let $f : X \rightarrow Y$ be a smooth morphism between smooth projective varieties over an algebraically closed field k .*

- (a) *If $\dim Y > 0$ then $-K_{X/Y}$ is not (absolutely) ample on X .*
- (b) *If X is Fano, then Y is also Fano.*

Proof. For (a), need to add.

For (b), we may assume $\dim Y > 0$. Pick an ample divisor H and $a > 0$ such that $-K_X - af^*H$ is nef. Let $h : C \rightarrow Y$ be a non-constant morphism from a smooth projective curve C . Consider $c \xrightarrow{f_C} X_C := X \times_Y C \xrightarrow{g} X$. Now $g^*(-K_X)$ is ample but $-K_{X_C/C}$ is not by (a). Hence for any $\varepsilon > 0$ there exists an irreducible curve $D \subset X_C$ such that $-K_{X_C/C} \cdot D < \varepsilon(-g^*K_X \cdot D)$. As $-K_{X_C/C} = g^*f^*K_Y - g^*K_X$, we have

$$-g^*f^*K_Y \cdot D > (1 - \varepsilon)(-g^*K_X \cdot D) \geq (1 - \varepsilon)(ag^*f^*H \cdot D).$$

One can choose $D \rightarrow C$ non-constant, so pushforward to C we have

$$\deg h^*(-K_Y) > (1 - \varepsilon)a \deg h^*H.$$

Hence since $\varepsilon > 0$ and $h : C \rightarrow Y$ are arbitrary, we know that $-K_Y - aH$ is nef. Hence $-K_Y$ is ample and Y is Fano. \square

Remark 1.5.5. *Note that if f is only flat, this is not true.*

1.5.2 Classifications Via Fano Index

Definition 1.5.6. Let X be a smooth Fano variety. The Fano index of X is

$$\text{Index}(X) := \max\{m \in \mathbb{N} : -K_X \sim mH \text{ for some Cartier divisor } H\}.$$

Theorem 1.5.7 (Kobayashi-Ochiai, 1970). Let X be a smooth Fano variety of dimension n over a field of characteristic zero. Then

(a) $\text{Index}(X) \leq n + 1$.

$$(b) \text{ Let } -K_X \sim \text{Index}(X)H, \text{ then } \chi(X, \mathcal{O}_X(jH)) = \begin{cases} 1 & j = 0 \\ 0 & -\text{Index}(X) < j < 0 \\ (-1)^n & j = -\text{Index}(X) \end{cases}.$$

Moreover we have

$$\chi(X, \mathcal{O}_X(tH)) = \begin{cases} \binom{t+n}{n} & \text{Index} = n + 1 \\ \binom{t+n+1}{n+1} - \binom{t+n-1}{n+1} & \text{Index} = n \\ H^n \binom{t+n-1}{n} + \binom{t+n-2}{n-2} & \text{Index} = n - 1 \\ H^n \binom{2t+n-2}{2n} \binom{t+n-2}{n-1} + \binom{t+n-2}{n-2} + \binom{t+n-3}{n-2} & \text{Index} = n - 2 \end{cases}.$$

$$\text{Hence } H^n = \begin{cases} 1 & \text{Index} = n + 1 \\ 2 & \text{Index} = n \end{cases} \text{ and } h^0(X, \mathcal{O}_X(H)) = \begin{cases} n + 1 & \text{Index} = n + 1 \\ n + 2 & \text{Index} = n \\ H^n + n - 1 & \text{Index} = n - 1 \\ \frac{1}{2}H^n + n & \text{Index} = n - 2 \end{cases}.$$

(c) $\text{Index}(X) = n + 1$ if and only if $X \cong \mathbb{P}^n$.

(d) $\text{Index}(X) = n$ if and only if $X \cong \mathbb{Q}^n \subset \mathbb{P}^{n+1}$ be a smooth quadric.

Proof. For (a), by Corollary 1.4.15 we can find a rational curve C such that $-K_X \cdot C \leq n + 1$. But $C \cdot H \geq 1$, hence $\text{Index}(X) \leq n + 1$.

For (b), $\chi(X, \mathcal{O}_X(jH))$ follows from Kodaira vanishing theorem and Serre duality. Then using this we know some roots of $\chi(X, \mathcal{O}_X(tH))$ correspond to t . Hence others are not hard to find. By Kodaira vanishing theorem again we get $h^0(X, \mathcal{O}_X(H))$ and H^n .

For (c), actually one can show that $\mathcal{O}_X(H)$ is base-point free by Claim V.1.11.7 in [15]. Hence by (b) this induce $p : X \rightarrow \mathbb{P}^n$. Let $Y := \text{Im}(p)$, then $1 = H^n = \deg p \deg Y$. Hence $\deg p = \deg Y = 1$. As H is ample, p is finite. Hence p is an isomorphism.

For (d), one can show that $\mathcal{O}_X(H)$ is base-point free by Claim V.1.11.7 in [15]. Hence by (b) this induce $p : X \rightarrow \mathbb{P}^{n+1}$. Let $Y := \text{Im}(p)$, then $2 = H^n = \deg p \deg Y$. As $\text{Index}(X) = n$, Y is not linear. Hence $\deg p = 1$ and $\deg Y = 2$. As H is ample, p is finite. Hence p is an isomorphism. \square

Remark 1.5.8. *Some remarks:*

- (1) *If one assumes only that $-K_X \sim mH$ is nef and big, then essentially the same proof gives that $X \cong \mathbb{P}^n$ if $m = n+1$. If $m = n$, then either X is a smooth quadric in $X \cong \mathbb{Q}^n \subset \mathbb{P}^{n+1}$ or $p : X \rightarrow Y$ is a birational morphism onto a singular quadric of rank 2.*
- (2) *Let X be a smooth Fano variety of dimension n (any characteristic) such that $-K_X \sim (n+1)H$, we also have $H^n = 1$.*

Indeed, section of $\mathcal{O}(mH)$ has $\binom{m+n-1}{n}$ conditions vanishing at $x \in X$. So if $H^n > 1$, then $H^0(X, \mathcal{O}_X(mH) \otimes \mathfrak{m}_x^{m+1}) \geq cm^n$ for some $c > 0$ (see also VI.2.15.7 in [15]). Pick a such section D . By Corollary 1.4.15 we can find a rational curve $x \in C \not\subset D$ such that $C \cdot D = m$ since $-K_X \sim (n+1)H$. But $C \cdot D \geq m+1$ which is impossible.

Theorem 1.5.9 (Fujita, 1990). *Let X be a smooth Fano variety of dimension $n \geq 3$ over a field of characteristic zero such that $\text{Index}(X) = n-1$. Assume $N^1(X) \cong \mathbb{R}$. Let $-K_X = (n-l)H$. Then one of the following holds:*

- (a) $H^n = 1$ and $X \cong X_6 \subset \mathbb{P}(1^{n-1}, 2, 3)$.
- (b) $H^n = 2$ and $X \cong X_4 \subset \mathbb{P}(1^n, 2)$.
- (c) $H^n = 3$ and $X \cong X_3 \subset \mathbb{P}(1^{n+1})$.
- (d) $H^n = 4$ and $X \cong X_{2,2} \subset \mathbb{P}(1^{n+2})$.
- (e) $H^n = 5$ and X is a linear space section of the Grassmannian $\text{Grass}(2, 5) \subset \mathbb{P}^9$ (thus $n \leq 6$).

Proof. See 8.11 in [7]. □

1.6 Application II: Boundedness of Fano Manifolds

Here we will give a brief introduction about the boundedness of Fano manifolds using rational curves due to Kollár-Miyaoka-Mori (see Section V.2 in [15] or original paper [17] for details). Then we will give a statement of BAB conjecture which has proved by Birkar. We consider schemes over an algebraically closed field k of characteristic zero.

Theorem 1.6.1 (Kollár-Miyaoka-Mori, 1992). *Let X be a smooth Fano variety of dimension n over k . Then there is a number $d(n)$ (depending only on n) such that any two points of X can be joined by an irreducible rational curve of anticanonical degree at most $d(\dim X)$.*

Proof. This follows from the rational connected varieties, see Section IV.3 and IV.4 and Corollary V.2.14.2 in [15]. □

Proposition 1.6.2. *Let X be a proper variety of dimension n , $x \in X$ a smooth point and \mathcal{L} an nef and big line bundle on X . Choose $d > 0$ such that a general point $x' \in X$ can be connected to x by an irreducible curve $C_{x'}$ such that $\mathcal{L} \cdot C_{x'} \leq d$. Then $\mathcal{L}^n \leq d^n$.*

Proof. Fix $\varepsilon > 0$ and use a classical result (see Corollary VI.2.15.7 in [15], actually with the similar proof of Remark 1.5.8(2)) there is a $k > 0$ and a divisor $D_k \in |k\mathcal{L}|$ such that $\text{mult}_x D_k \geq k \sqrt[n]{\mathcal{L}^n} - k\varepsilon$. Pick a general point $x' \notin \text{supp } D_k$. Then $C_{x'}$ is not contained in D_k hence

$$kd \geq D_k \cdot C_{x'} \geq \text{mult}_x D_k \geq k \sqrt[n]{\mathcal{L}^n} - k\varepsilon.$$

Hence $d \geq \sqrt[n]{\mathcal{L}^n} - \varepsilon$ and let $\varepsilon \rightarrow 0$. \square

Theorem 1.6.3 (Boundedness of Fano Manifolds, Kollár-Miyaoka-Mori 1992). *All n -dimensional Fano Manifolds over k forms a bounded family.*

Proof. By Theorem 1.6.1 and Proposition 1.6.2, we know that $(-1)^n K_X^n$ is bounded. Using Matsusaka estimate (see Exercise VI.2.15.8 in [15], proved by Kollár-Matsusaka in [16] in 1983) we know that for any nef and big divisor H , the coefficients of polynomial $\chi(X, \mathcal{O}_X(tH))$ can be bounded by H^m and $K_X \cdot H^{m-1}$. So $\chi(X, \mathcal{O}_X(tK_X))$ has bounded coefficients. In 1970, Matsusaka in [18] shows that there are only finitely many deformation types with fixed Hilbert polynomial. So All n -dimensional Fano Manifolds over k forms a bounded family. \square

This finish the story of the smooth Fano varieties. If we have some mild singularities, then this problem is the famous conjecture in birational geometry:

Theorem 1.6.4 (BAB-Conjecture, Birkar 2016). *Let $d \in \mathbb{N}$ and $\varepsilon > 0$. Then the set of projective varieties X such that (X, B) is ε -lc of dimension d for some boundary B and $-(K_X + B)$ is nef and big, form a bounded family.*

Some History. This is one of the fundamental result of singular Fano varieties and is one of the most important conjectures in birational geometry and it is related to the termination of flips.

As we have seen, Kollár-Miyaoka-Mori in 1992 showed the boundedness of smooth Fano varieties using rational curves. But this can not be used in the BAB-conjecture.

In 1992 Kawamata showed the boundedness of terminal \mathbb{Q} -Fano \mathbb{Q} -factorial threefolds of Picard number one. In 1992 Borisov-Borisov shows this for toric cases. In 1994 V. Alexeev proved the BAB-conjecture for surfaces. In 2000 Kollár-Miyaoka-Mori-Takagi showed the boundedness of canonical \mathbb{Q} -Fano threefolds. Then in 2014 C. Jiang proved the weak BAB-conjecture for 3-fold, which is an important step towards the BAB-conjecture.

Finally BAB-Conjecture (along with the Weak BAB Conjecture) in arbitrary dimension was proved by C. Birkar in 2016 by different and much stronger methods, see his papers [4] and [5]. \square

Remark 1.6.5. *The theory of moduli of Fano varieties is an application of J. Alper's theory of good moduli space. Many mathematicians build the whole theory in recent years using K-stability theory.*

In fact, by the theory of Birkar in [4], C. Jiang in 2017 showed that any K-semistable Fano varieties with dimension n and volume $(-K_X)^n = V$ is bounded. Then there exists $N \gg 0$ such that $|-NK_X|$ gives an embedding to \mathbb{P}^M . Fix a Hilbert polynomial and then using the theory of KSBA-moduli space, there is a subspace of that Hilbert space H' correspond what we want. Hence the moduli stack $\mathcal{M}_{n,V}^{\text{Kss}}$ of K-semistable Fano varieties with dimension n and volume $(-K_X)^n = V$ is $[H'/\text{PGL}]$ which is an algebraic stack of finite type. Then using Alper's theory we construct the separated good moduli space $\mathcal{M}_{n,V}^{\text{Kss}} \rightarrow M_{n,V}^{\text{Kps}}$ with ample CM-line bundle.

1.7 Application III: Hartshorne's Conjecture

Hartshorne's Conjecture is first proved by S. Mori in his famous and important paper [19]. This paper is the beginning of the theory of VMRT.

Theorem 1.7.1 (Hartshorne's Conjecture, Mori 1979). *Consider n -dimensional smooth projective variety X over an algebraically closed field k , if T_X is ample then $X \cong \mathbb{P}_k^n$.*

Proof. By Theorem 1.7.3 directly. \square

This conjecture motivated by an important conjecture in complex geometry:

Theorem 1.7.2 (Frankel's Conjecture, Mori 1979 and Siu-Yau 1980). *If X is a compact Kähler manifold of dimension n with everywhere positive holomorphic bisectional curvature, then $X \cong \mathbb{P}_{\mathbb{C}}^n$.*

Proof. By Kodaira embedding theorem to $-K_X$ we know that X is a projective manifold. Then by Theorem 1.7.1 we get the result. \square

Our main result in this section is the following due to Mori which is much stronger than the Hartshorne's Conjecture as we mentioned above.

Theorem 1.7.3 (Mori, 1979). *Consider n -dimensional smooth projective variety X over an algebraically closed field k . If*

- (1) $-K_X$ is ample, that is, X is a Fano manifold;
- (2) For any non-constant morphism $f : \mathbb{P}_k^1 \rightarrow X$ the bundle f^*T_X is the sum of line bundles of positive degree.

Then $X \cong \mathbb{P}_k^n$.

Proof. We will use the following lemmas:

- **Lemma A.** For any $f : \mathbb{P}_k^1 \rightarrow X$ such that bundle f^*T_X is the sum of line bundles of positive degree, we have $\deg f^*T_X \geq n+1$. If equality holds, then f is an closed embedding and is standard, that is, $f^*T_X \cong \mathcal{O}(2) \oplus \mathcal{O}(1)^{\oplus n-1}$.

Proof of Lemma A. Let $f^*T_X \cong \mathcal{O}(a_1) \oplus \cdots \oplus \mathcal{O}(a_n)$ where $a_1 \geq \cdots \geq a_n$. Then $a_i \geq 1$ and $a_1 \geq 2$ by Remark 1.3.10. Hence $\deg f^*T_X \geq n+1$. If equality holds, then the only possibility is $f^*T_X \cong \mathcal{O}(2) \oplus \mathcal{O}(1)^{\oplus n-1}$. To show f is an embedding, first we now that f is unramified by trivial reason. Others are also easy and we refer to Lemma V.3.7.3.2 in [15]. \square

- **Lemma B.** In the case of Theorem, any rational curve can be deformed as a cycle to the sum of rational curves C such that $-K_X \cdot C = n+1$.

Proof of Lemma B. From bend and break directly. \square

Back to the theorem. We let $n \geq 2$. Pick $f : \mathbb{P}^1 \rightarrow X$ passing a general point $x \in X$ with $0 \mapsto x$ and with minimal degree $n+1$ by Lemma B. By Proposition 1.3.11 the components $V \subset \mathbf{Hom}_{\text{bir}}^n(\mathbb{P}^1, X; 0 \mapsto x) = \mathbf{Hom}_{\text{bir}}(\mathbb{P}^1, X; 0 \mapsto x)$ containing $[f]$ is smooth of dimension $n+1$ and the correspond $\mathcal{K}_x \subset \mathbf{RatCurves}_{n+1}^n(x, X)$ is also smooth of dimension $n-1$. Actually $\gamma : V \rightarrow \mathcal{K}_x$ is a principal $G := \text{Aut}(\mathbb{P}^1; 0)$ -bundle.

► **Step 1.** We claim that $\mathcal{K}_x \cong \mathbb{P}(\Omega_{X,x}^1)$.

Consider the tangent $\Phi : V \rightarrow \mathbb{V}(\Omega_{X,x}^1)$ via $v \mapsto (dv)_0(\frac{d}{dt})$ for uniformizer $t \in \mathcal{O}_{\mathbb{P}^1,0}$ by Lemma A. First we claim that Φ is smooth. Easy to see that Φ is flat and we just need to show $\Phi^{-1}(\Phi(v))$ is smooth. Note that for any finite type k -scheme T and for any morphism $T \rightarrow V$ over k , it factors through $\Phi^{-1}(\Phi(v)) \rightarrow V$ if and only if the morphism $\mathbb{P}_T^1 \rightarrow X_T$ coincides on $\text{Spec}(\mathcal{O}_{\mathbb{P}^1,0}/\mathfrak{m}_{\mathbb{P}^1,0}^2)$ with v_T . Hence

$$\Phi^{-1}(\Phi(v)) \cong V \cap \mathbf{Hom}_{\text{bir}}(\mathbb{P}^1, X; v|_{\text{Spec}(\mathcal{O}_{\mathbb{P}^1,0}/\mathfrak{m}_{\mathbb{P}^1,0}^2)})$$

which is open and hence smooth with the same proof of Proposition 1.3.11.

Hence by Lemma A again we get a smooth morphism $\Phi : \mathcal{K}_x \rightarrow \mathbb{P}(\Omega_{X,x}^1)$. Hence it is finite étale. Hence $\mathcal{K}_x \cong \mathbb{P}(\Omega_{X,x}^1)$.

► **Step 2.** Let $F : V \times \mathbb{P}^1 \rightarrow \mathcal{K}_x \times X$ defined by $(v, x) \mapsto (\gamma(v), v(x))$, consider $Z := \underline{\text{Spec}}_{\mathcal{K}_x \times X} F_* \mathcal{O}^G$ which is a geometrically quotient by G (can be checked along the principal bundle $V \rightarrow \mathcal{K}_x$). As $\psi : Z \rightarrow \mathcal{K}_x$ is a \mathbb{P}^1 -bundle with a section $S \subset Z$ induced by $V \rightarrow V \times \mathbb{P}^1$ as $v \mapsto (v, 0)$, then $Z \cong \mathbb{P}(\psi_* \mathcal{O}_Z(S))$ is a projective bundle. Define a universal cycle map $\pi : Z \rightarrow X$ induced by G -invariant cycle morphism $V \times \mathbb{P}^1 \rightarrow X$. We claim that $\pi : Z \rightarrow X$ is étale on $Z \setminus S$ and $\pi(S) = x$.

Actually $\pi(S) = x$ is trivial, to show $\pi|_{Z \setminus S}$ is étale we just need to show $V \times \mathbb{P}^1 \rightarrow X$ is smooth. This follows from Corollary 1.3.4 and Theorem 1.3.6. Hence we get the claim.

► **Step 3.** Consider the Stein factorization we have $\pi : Z \xrightarrow{\phi} U \cong \underline{\text{Spec}}_X \pi_* \mathcal{O}_Z \xrightarrow{\eta} X$. We claim that η is étale, $Z \setminus S \cong U \setminus \{r\}$ where $\phi(S) = r$ and $\mathcal{O}_S(S) \cong \mathcal{O}_{\mathbb{P}^{n-1}}(-1)$.

In fact by Stein factorization η is étale outside a codimension ≥ 2 locus, by purity of branched locus we know that η is étale. Now $Z \setminus S \cong U \setminus \{r\}$ where $\phi(S) = r$ follows from Zariski main theorem. Finally we show that $\mathcal{O}_S(S) \cong \mathcal{O}_{\mathbb{P}^{n-1}}(-1)$. Indeed, pick a hyperplane $L \subset \mathcal{K}_x$ and a line $C \cong \mathbb{P}^1 \subset S$ such that $\psi(C) \not\subset L$. Let $D := \psi^{-1}(L)$, then $C \cdot D = 1$. As $r \in \phi(D)$, we have $\phi^{-1}\phi(D) = D + aS$ for some $a > 0$. So $C \cdot \phi^{-1}\phi(D) = \phi(D) \cdot D = 0$. Hence $C \cdot S = -1$ and $\mathcal{O}_S(S) \cong \mathcal{O}_{\mathbb{P}^{n-1}}(-1)$.

► **Step 4.** We claim that $U \cong \mathbb{P}^n$.

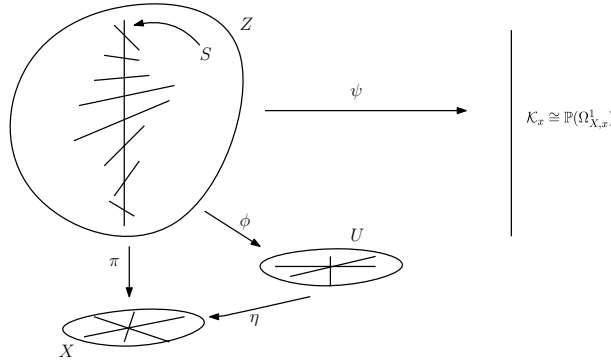

By Step 3 we have $\mathcal{O}_S(S) \cong \mathcal{O}_{\mathbb{P}^{n-1}}(-1)$, hence

$$0 \rightarrow \mathcal{O}_Z \rightarrow \mathcal{O}_Z(S) \rightarrow \mathcal{O}_S(-1) \rightarrow 0$$

exact. Since $R^1\psi_* \mathcal{O}_Z = 0$, we get

$$0 \rightarrow \mathcal{O}_{\mathcal{K}_x} \rightarrow \psi_* \mathcal{O}_Z(S) \rightarrow \mathcal{O}_{\mathcal{K}_x}(-1) \rightarrow 0$$

exact. As $\text{Ext}_{\mathbb{P}^{n-1}}^1(\mathcal{O}(-1), \mathcal{O}) = 0$, we get $\psi_* \mathcal{O}_Z(S) \cong \mathcal{O}_{\mathcal{K}_x} \oplus \mathcal{O}_{\mathcal{K}_x}(-1)$. Hence by Step 2 we have $Z \cong \mathbb{P}(\mathcal{O}_{\mathcal{K}_x} \oplus \mathcal{O}_{\mathcal{K}_x}(-1))$.

Hence $Z \cong \mathbb{P}(\mathcal{O}_{\mathcal{K}_x} \oplus \mathcal{O}_{\mathcal{K}_x}(-1)) \cong \text{Bl}_O \mathbb{P}^n$. We can have a contraction map $Z \rightarrow \text{Bl}_O \mathbb{P}^n$ makes S to a point $O \in \mathbb{P}^n$ (in fact it is induced by $\psi^* \mathcal{O}(1) \otimes \mathcal{O}(S)$). Hence via $\mathbb{P}^n \leftarrow Z \rightarrow U$ we have a birational map $\mathbb{P}^n \dashrightarrow U$. This must be an isomorphism since $Z \cong \text{Bl}_O \mathbb{P}^n$ has only two dimensional Mori cone, hence the only birational contraction is this one (another is that \mathbb{P}^1 -bundle).

► **Step 5.** Finish the proof, that is, we have $X \cong \mathbb{P}^n$.

Since \mathbb{P}^n is simply connected, $U \cong \mathbb{P}^n \rightarrow X$ is a Galois covering by Step 3 and 4. Thus $X \cong \mathbb{P}^n$ because any automorphism of \mathbb{P}^n has a fixed point. \square

Remark 1.7.4. Note that by the proof this is right if we just consider the rational curves containing a sufficient general point.

Corollary 1.7.5 (Lazarsfeld, 1984). *Let X be a smooth projective variety over an algebraically closed field k of dimension > 0 . Let there be a surjective separable morphism $p : \mathbb{P}_k^n \rightarrow X$, then $X \cong \mathbb{P}^n$.*

Proof. By the Chow ring structure of projective space, we know that $\dim X = n$ and p is finite. Hence let R be a ramification divisor of p , we have $p^*(-K_X) = -K_{\mathbb{P}^n} + R$ hence some multiple of $-K_X$ is effective. As p surjective, then $\dim N_1(X) = 1$ Hence $-K_X$ is ample and X is Fano. For a sufficient general point $x \in X$ outside of the ramification divisor, consider $f : \mathbb{P}^1 \rightarrow X$ as $0 \mapsto x$. Let C be a normalization of a component in $\mathbb{P} \times_X \mathbb{P}^1$, we have

$$\begin{array}{ccc} C & \xrightarrow{h} & \mathbb{P}^n \\ \downarrow q & & \downarrow p \\ \mathbb{P}^1 & \xrightarrow{f} & X \end{array}$$

The natural map $r : h^*T_{\mathbb{P}^n} \rightarrow h^*p^*T_X = q^*f^*T_X$ is a local isomorphism $q^{-1}(0) \subset C$ since p is étale above x . Write $f^*T_X = \bigoplus_i \mathcal{O}_{\mathbb{P}^1}(a_i)$. For any j we have

$$\bigoplus h^*\mathcal{O}_{\mathbb{P}^1}(1) \rightarrow h^*T_{\mathbb{P}^n} \xrightarrow{r} \bigoplus_i q^*\mathcal{O}_{\mathbb{P}^1}(a_i) \rightarrow q^*\mathcal{O}_{\mathbb{P}^1}(a_j)$$

which is surjective over an open subspace $U \subset C$. So $q^*\mathcal{O}_{\mathbb{P}^1}(a_j)$ has a section vanishing at some point. Hence $a_i > 0$ for any i . So by Theorem 1.7.3 we have $X \cong \mathbb{P}^n$. \square

Chapter 2

Varieties of Minimal Rational Tangents

We will assume the base field is \mathbb{C} .

2.1 Basic Properties

In this section we will discover some fundamental and important properties of tangent map $\tau_x : \mathcal{K}_x \dashrightarrow \mathbb{P}(\Omega_{X,x}^1)$ with VMRT \mathcal{C}_x for any smooth Fano variety X . First we need to find some properties of singular rational curves.

Definition 2.1.1. *Let X be a smooth Fano variety over \mathbb{C} and $x \in X$ is a point. Choose a (dominated) minimal rational component $\mathcal{K} \subset \text{RatCurves}_{p+2}^n(X)$ and the corresponding component $\mathcal{K}_x \subset \text{RatCurves}_{p+2}^n(x, X)$ be of minimal degree $p+2$. Consider the rational map*

$$\tau_x : \mathcal{K}_x \dashrightarrow \mathbb{P}(\Omega_{X,x}^1), \quad [f : \mathbb{P}^1 \rightarrow X] \mapsto \left. \frac{df}{dt} \right|_{t=0}$$

where t be the uniformizer of $\mathfrak{m}_0 \subset \mathcal{O}_{\mathbb{P}^1,0}$, defined on curves smooth at x . We define the variety of minimal rational tangents or VMRT $\mathcal{C}_x \subset \mathbb{P}(\Omega_{X,x}^1)$ at x is the closure of the image of τ_x .

Remark 2.1.2. *Note that there are only finitely many choice of minimal rational component $\mathcal{K} \subset \text{RatCurves}_{p+2}^n(X)$, hence there are only finitely many choice of $\mathcal{C}_x \subset \mathbb{P}(\Omega_{X,x}^1)$, at least for general point $x \in X$.*

Theorem 2.1.3 (Kebekus [12], 2002). *Let X be a smooth Fano variety and $\mathcal{K} \subset \text{RatCurves}_{p+2}^n(X)$ a (dominated) minimal rational component. Let $\mathcal{K}'_x \subset \mathcal{K}$ be the locus*

of curves passing through x where $x \in X$ be a general point (hence $\mathcal{K}_x \rightarrow \mathcal{K}'_x$ is a normalization). consider the closed subvarieties

$$\mathcal{K}_x^{\text{sing}} := \{[C] \in \mathcal{K}'_x : C \text{ singular}\}, \quad \mathcal{K}_x^{\text{sing},x} := \{[C] \in \mathcal{K}'_x : C \text{ singular at } x\}.$$

Then the following holds.

- (a) The space $\mathcal{K}_x^{\text{sing}}$ has dimension at most one, and the subspace $\mathcal{K}_x^{\text{sing},x}$ is at most finite. Moreover, if $\mathcal{K}_x^{\text{sing},x}$ is not empty, the associated curves are unramified.
- (b) If there exists a line bundle $\mathcal{L} \in \text{Pic}(X)$ that intersects the curves with multiplicity 2, then $\mathcal{K}_x^{\text{sing}}$ is at most finite and $\mathcal{K}_x^{\text{sing},x}$ is empty.

Proof. See the original paper [12] or the sketch in Theorem 2.12 in the survey [13]. \square

Remark 2.1.4. This theorem is right for normal varieties covered by rational curves.

By this Theorem 2.1.3(a) directly we have the following fundamental result:

Corollary 2.1.5. Every curve parametrized by \mathcal{K}_x is unramified at x (i.e., its normalization is unramified at $0 \mapsto x$).

Theorem 2.1.6 (Kebekus-2002, Hwang-Mok-2004). Let X be a smooth Fano variety and $\mathcal{K} \subset \text{RatCurves}_{p+2}^n(X)$ a (dominated) minimal rational component. Let $x \in X$ be a general point, consider the tangent map

$$\tau_x : \mathcal{K}_x \dashrightarrow \mathbb{P}(\Omega_{X,x}^1), \quad [f : \mathbb{P}^1 \rightarrow X] \mapsto \left. \frac{df}{dt} \right|_{t=0}.$$

- (a) τ_x is actually a finite morphism, we can call it *tangent morphism*.
- (b) $\tau_x : \mathcal{K}_x \rightarrow \mathcal{C}_x$ is a birational morphism, hence
- (c) $\tau_x : \mathcal{K}_x \rightarrow \mathcal{C}_x$ is the normalization.

Proof. (a) and (b) implies (c) in this case.

For (a) (proved in [12]), we will first show that $\tau_x : \mathcal{K}_x \dashrightarrow \mathbb{P}(\Omega_{X,x}^1)$ actually can be a morphism. We have two arguments with the same result:

(M1) By Theorem 1.2.8(b) we have q as follows

$$\begin{array}{ccc} \mathcal{K}_x & \xrightarrow{q} & \text{Hom}_{\text{bir}}(\mathbb{P}^1, X; 0 \mapsto x) / \text{Aut}(\mathbb{P}^1; 0) \\ & \searrow \tau_x & \downarrow t_x \\ & & \mathbb{P}(\Omega_{X,x}^1) \end{array}$$

where $t_x : \text{Hom}_{\text{bir}}(\mathbb{P}^1, X; 0 \mapsto x) / \text{Aut}(\mathbb{P}^1; 0) \rightarrow \mathbb{P}(\Omega_{X,x}^1)$ sends f to $(df)_0(\frac{d}{dt})$ for uniformizer $t \in \mathcal{O}_{\mathbb{P}^1,0}$ since it is unramified by Corollary 2.1.5.

(M2) Consider the universal morphism and cycle morphism

$$\begin{array}{ccc} \mathrm{Univ}^n(x, X) & \longleftarrow & \mathcal{U}_x^n \xrightarrow{\iota_x} X \\ & & \downarrow \pi_x \\ \mathrm{RatCurves}^n(x, X) & \longleftarrow & \mathcal{K}_x \end{array}$$

We have a section $\mathcal{K}_x \cong \sigma_\infty \subset \mathcal{U}_x^n$ contracted to $x \in X$ via ι_x . By Corollary 2.1.5 again we can consider a nowhere vanishing morphism of vector bundles

$$T_{\mathcal{U}_x^n/\mathcal{K}_x}|_{\sigma_\infty} \rightarrow \iota_x^*(T_{X,x})$$

and taking the projectivization we get the result.

Now we need to show τ_x is finite. If not, we have a curve $C \subset \mathcal{K}_x$ contracted by τ_x . Let the normalization of universal family $U \rightarrow C$ is again a \mathbb{P}^1 -bundle. Let the corresponding section is $s_\infty \subset U$. Consider $N_{s_\infty/U}$. Since s_∞ contracted into a point, its normal bundle is negative. But this is the tangent morphism, the normal bundle need to be trivial. This is impossible. Hence τ_x is finite.

For (b), proved in [11] □

Proposition 2.1.7.

Proof. We follows Proposition 1.4 in the survey [10] and Proposition 2.7 in [2]. □

Remark 2.1.8. Hence we give another proof of that τ_x is generically finite.
